

HSPF for Water Balance Inputs to MODFLOW for NFSEG 1.0

Tim Cera, P.E.

Senior Professional Engineer

St. Johns River Water Management District

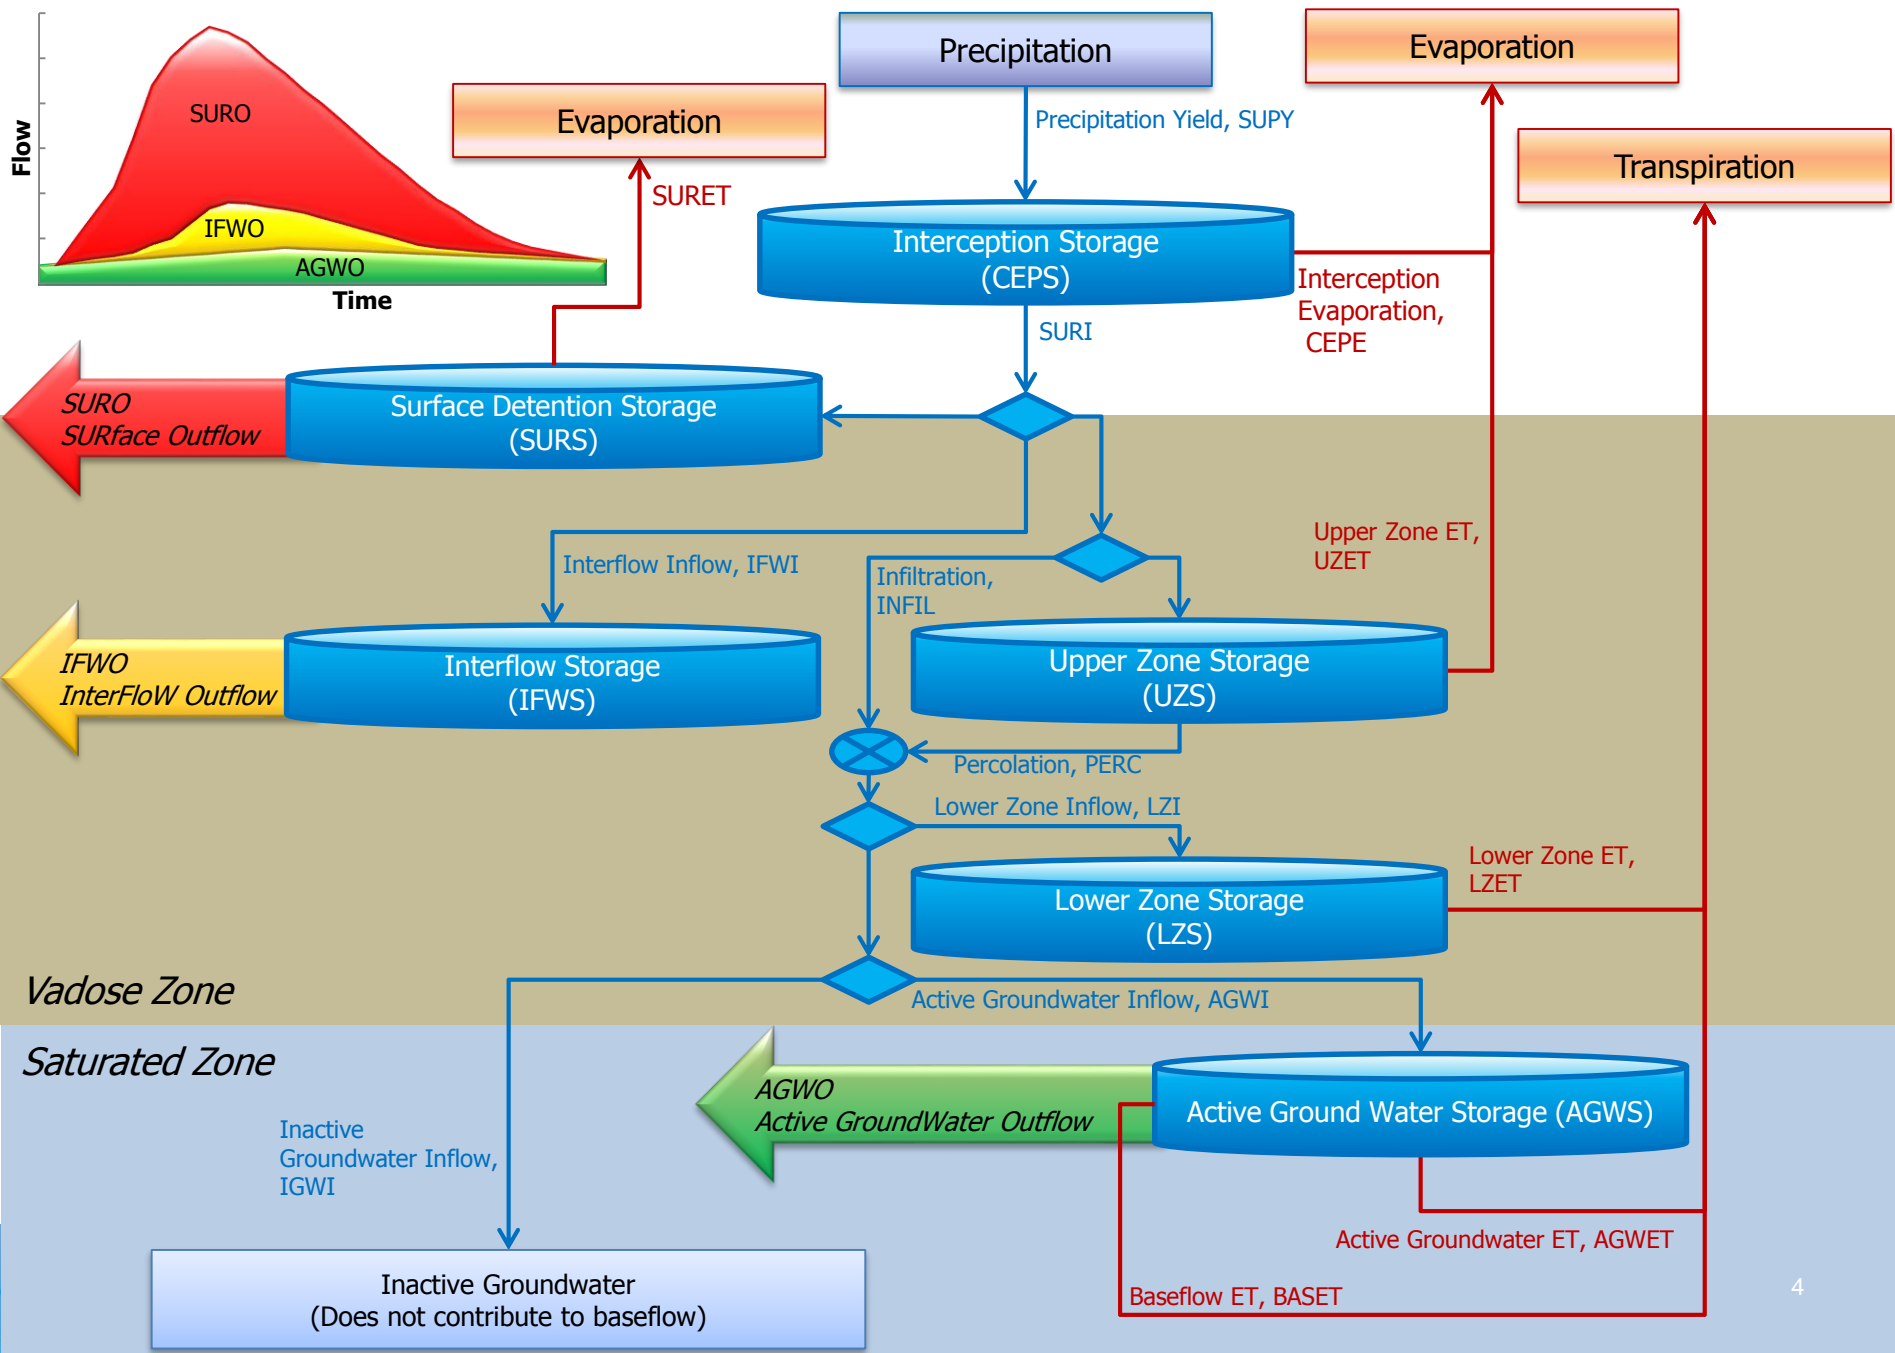

NFSEG

- HSPF
 - Recharge
 - Maximum saturated ET for Evapotranspiration Package

MODFLOW Inputs

- Recharge is the sum of Active Groundwater Inflow (AGWI) and Inactive Groundwater Inflow (IGWI)

Recharge = AGWI+IGWI

- PET is input as demand
- Maximum Saturated ET is PET minus all unsaturated ET values

MSATET = PET-CEPE-UZET-LZET

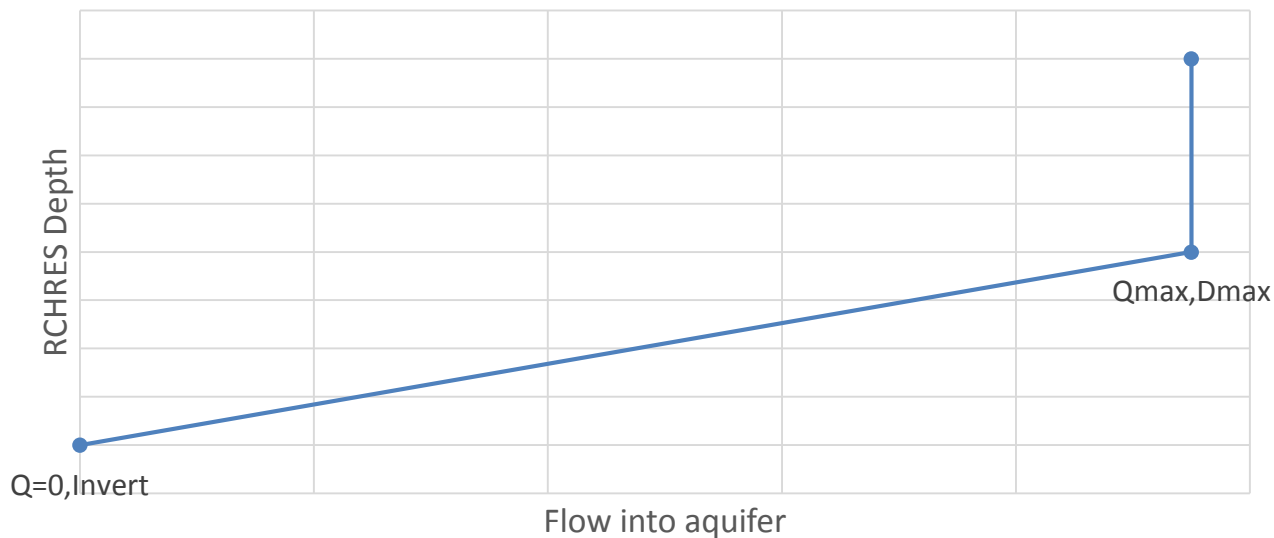

Closed Basins

- Traditionally are not modeled since they do not contribute to surface flows
- Naive approach would be to increase IGWI until surface flow is 0
 - Distorts the infiltration and evaporation parameters
- NFSEG Methodology
 - Use calibrated parameters from nearby subwatersheds for infiltration and evaporation
 - Increase IGWI to high, but reasonable values
 - All closed basins had NHDPlus identified swallets
 - Apply the drainage well concept, but configure as a sink

Swallets and Drainage Wells

- Composite of all swallets and drainage wells in subwatershed
- Simple linear flow relationship
 - Linear representing flow controlled by opening
 - Maximum representing flow controlled by aquifer
- Well invert, Q_{\max} , D_{\max} parameterized by PEST

Tributary Reach

Closed Basins: Swallets and Drainage Wells

Springs Plus Diffuse Groundwater Discharge to a Reach (Aggregate Discharge)

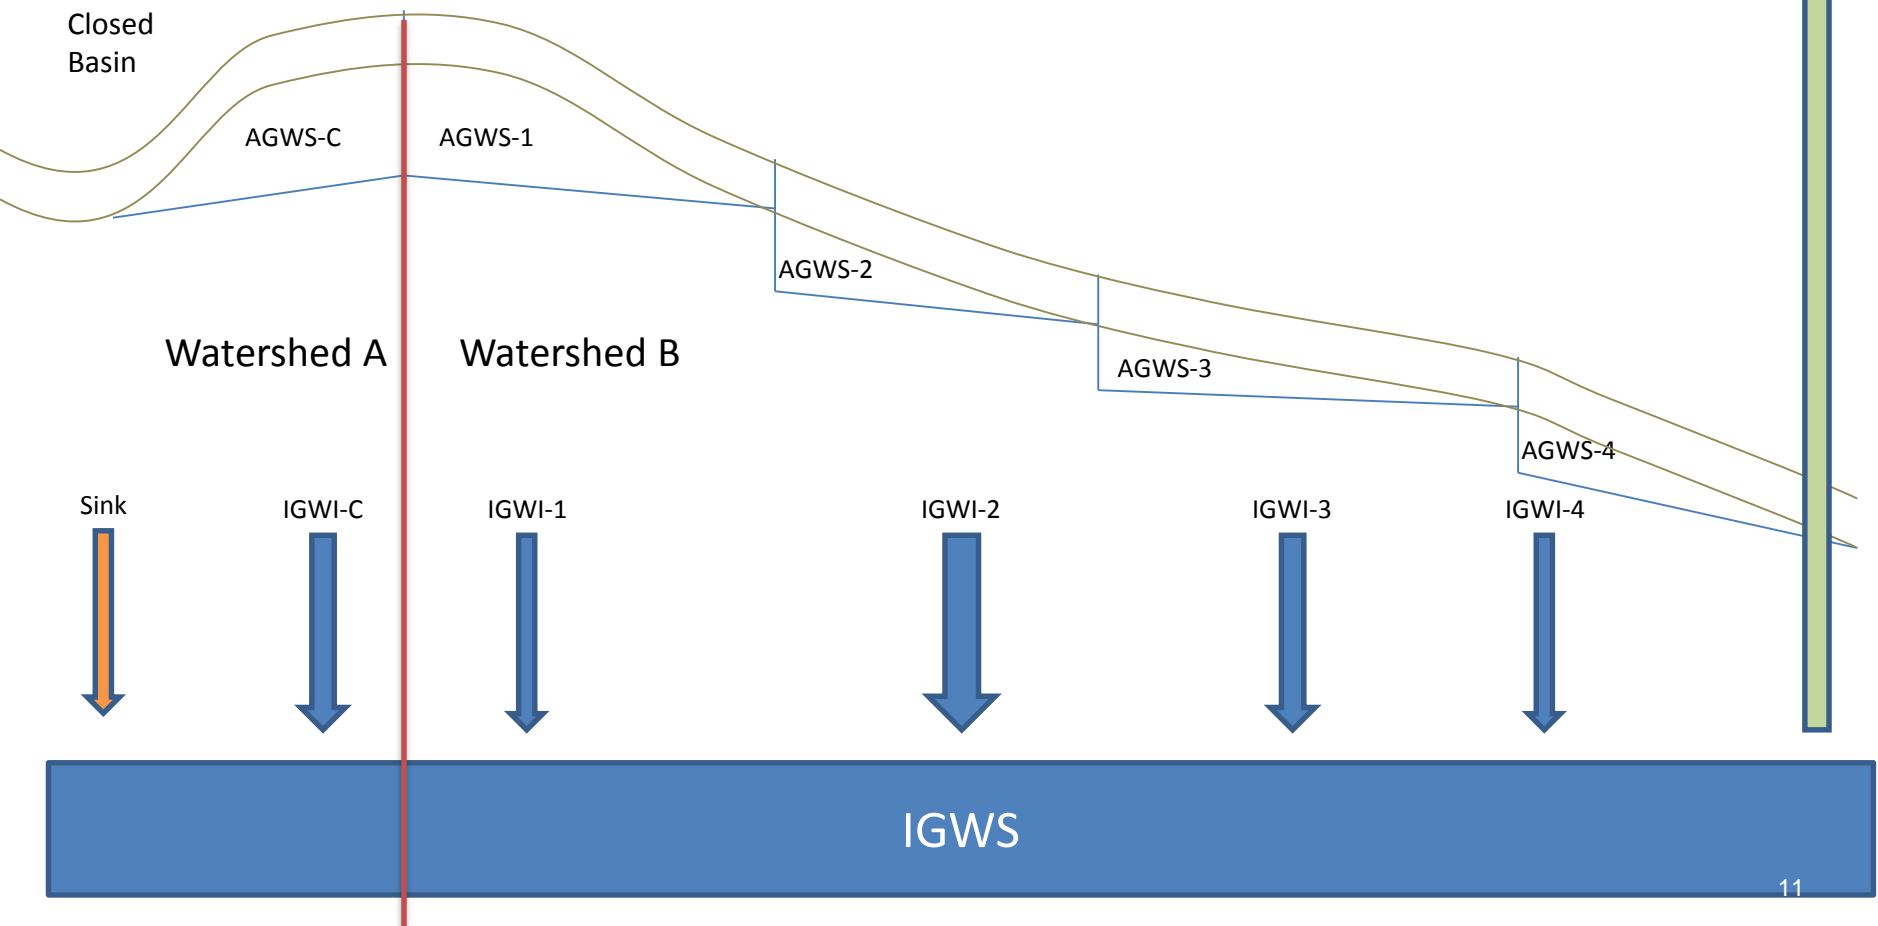

- Traditional Approach
 - Inactive Groundwater Inflow (IGWI) goes out of the model
 - Springs are observed flow time-series imposed into a RCHRES
- Inactive Groundwater Storage Approach
 - IGWI and sink flow is collected within the springshed into an “underground RCHRES reservoir”
 - Flow from the underground RCHRES reservoir is used to represent the aggregate discharge within the springshed

Ichetucknee Springs

HSPF Water Use: NFSEG

- NFSEG HSPF models
 - Agricultural irrigation
 - Domestic Self Supply
 - Public Water Supply
 - Septic fields
 - Golf courses
 - Reuse spray fields

Post-Processing

- Develop PERLND ID raster
 - National Land Cover Database (NLCD) 30x30 meter
 - Subwatershed raster
- Develop Look Up Table (LUT)
 - hspfbintoolbox to develop PERLND ID to model output (LUT)
- ViRTual (VRT) spatial dataset
 - http://www.gdal.org/drv_vrt.html
 - Allows for efficient transformation of PERLND ID raster to model output raster using LUT
- QGIS is used for visualization of VRTs (<http://qgis.org>)
- Zonal statistics to get average across MODFLOW cell
