1. INTRODUCTION

The Wekiva River watershed is a part of the Middle St. Johns River Basin, and is located in Lake, Seminole, Orange, and Marion counties (Figure 1). The Wekiva River watershed drains an area of approximately 376 square miles to the St. Johns River, and is comprised of four principal watercourses: the Wekiva River, the Little Wekiva River, Black Water Creek and Rock Springs Run. Many named springs (>30) exist in the watershed, including Wekiwa Springs, Rock Springs, Seminole Springs, Sanlando Springs, and Messant Spring. Discharges from the springs contribute to a significant portion of flow in the Wekiva River.

The St. Johns River Water Management District (SJRWMD) is mandated by statute to establish minimum surface water flows and levels (MFLs) for priority water bodies (Section 373.042, Florida Statutes (F.S.)). SJRWMD identified priority water bodies within the Wekiva River Basin including the Wekiva River at SR 46, the Little Wekiva River and associated springs, Rock Springs and Run, and Wekiwa Springs as priority systems that are scheduled to have an MFL established or reevaluated by 2019. The objective of this work is to develop hydrologic and hydraulic models to support the re-evaluation and determination of the MFLs in the Wekiva River watershed. The previous Hydrological Simulation Program – FORTRAN (HSPF) model that was developed to simulate the hydrology of the Wekiva River watershed was updated for this study. The HSPF model uses the land use, rainfall, evaporation, spring flows, and stream flow data in the watershed to perform long-term flow simulations in the Wekiva River watershed. The existing HEC-RAS, steady state one-dimensional river hydraulics model was updated and extended to include the Little Wekiva River and Rock Springs Run, as well as Wekiva River to simulate the water surface profiles of the Wekiva River system. In addition, a dynamic HEC-RAS model simulation was conducted in this study. The HEC-RAS model is used to convert the flows simulated by the HSPF into stages and to calculate the stages at other transect locations along the Wekiva River. Results from these two models will be used to determine and evaluate the MFLs.

This report documents the hydrologic and hydraulic modeling process for MFLs evaluations. Section 2 provides descriptions of key characteristics of the Wekiva River watershed and the dataset used for surface water modeling. Sections 3 and 4 describe the development of HSPF and HEC-RAS models for hydrologic and hydraulic simulations. Section 5 summarizes the results of this study. The use of these models for MFLs evaluations will be presented in a separate report.

The HSPF and HEC-RAS models were peer reviewed by two modeling experts in late 2018. Peer review comments were incorporated into the final models and this report.

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLs EVALUATIONS

2. DATA COLLECTION AND PREPARATION

2.1 WATERSHED DELINEATION

The Wekiva River watershed was divided into 44 sub-watersheds. The watershed boundaries were defined using elevation and terrain models developed by SJRWMD. These sub-watersheds can be grouped into three major sub-basins: Black Water Creek watershed (sub-watersheds 1 – 13), Wekiva River watershed (sub-watersheds 14 – 19, 26 – 29, 39 – 43), and Little Wekiva River watershed (sub-watersheds 20 – 25, 30 – 38, 44), as shown in Figure 2. Black Water Creek and the Little Wekiva River are major tributaries to the Wekiva River.

In addition, there are three tributaries: Rock Springs Run, Sulphur Run, and Seminole Creek. Rock Springs Run drains to the Wekiva River directly. Sulphur Run and Seminole Creek drain to Black Water Creek first, and then to the Wekiva River. The drainage areas of Rock Springs Run, Sulphur Run, and Seminole Creek are sub-watersheds 14 – 17, sub-watershed 11, and sub-watersheds 9 – 10, respectively. Sub-watersheds 38-44 are closed drainage areas and do not contribute surface runoff to downstream areas. Outflows from these closed drainage areas recharge groundwater. The contributions from these closed sub-watersheds to the Wekiva River are assumed to occur through the nearby springs; thus, not simulated directly in the HSPF model.

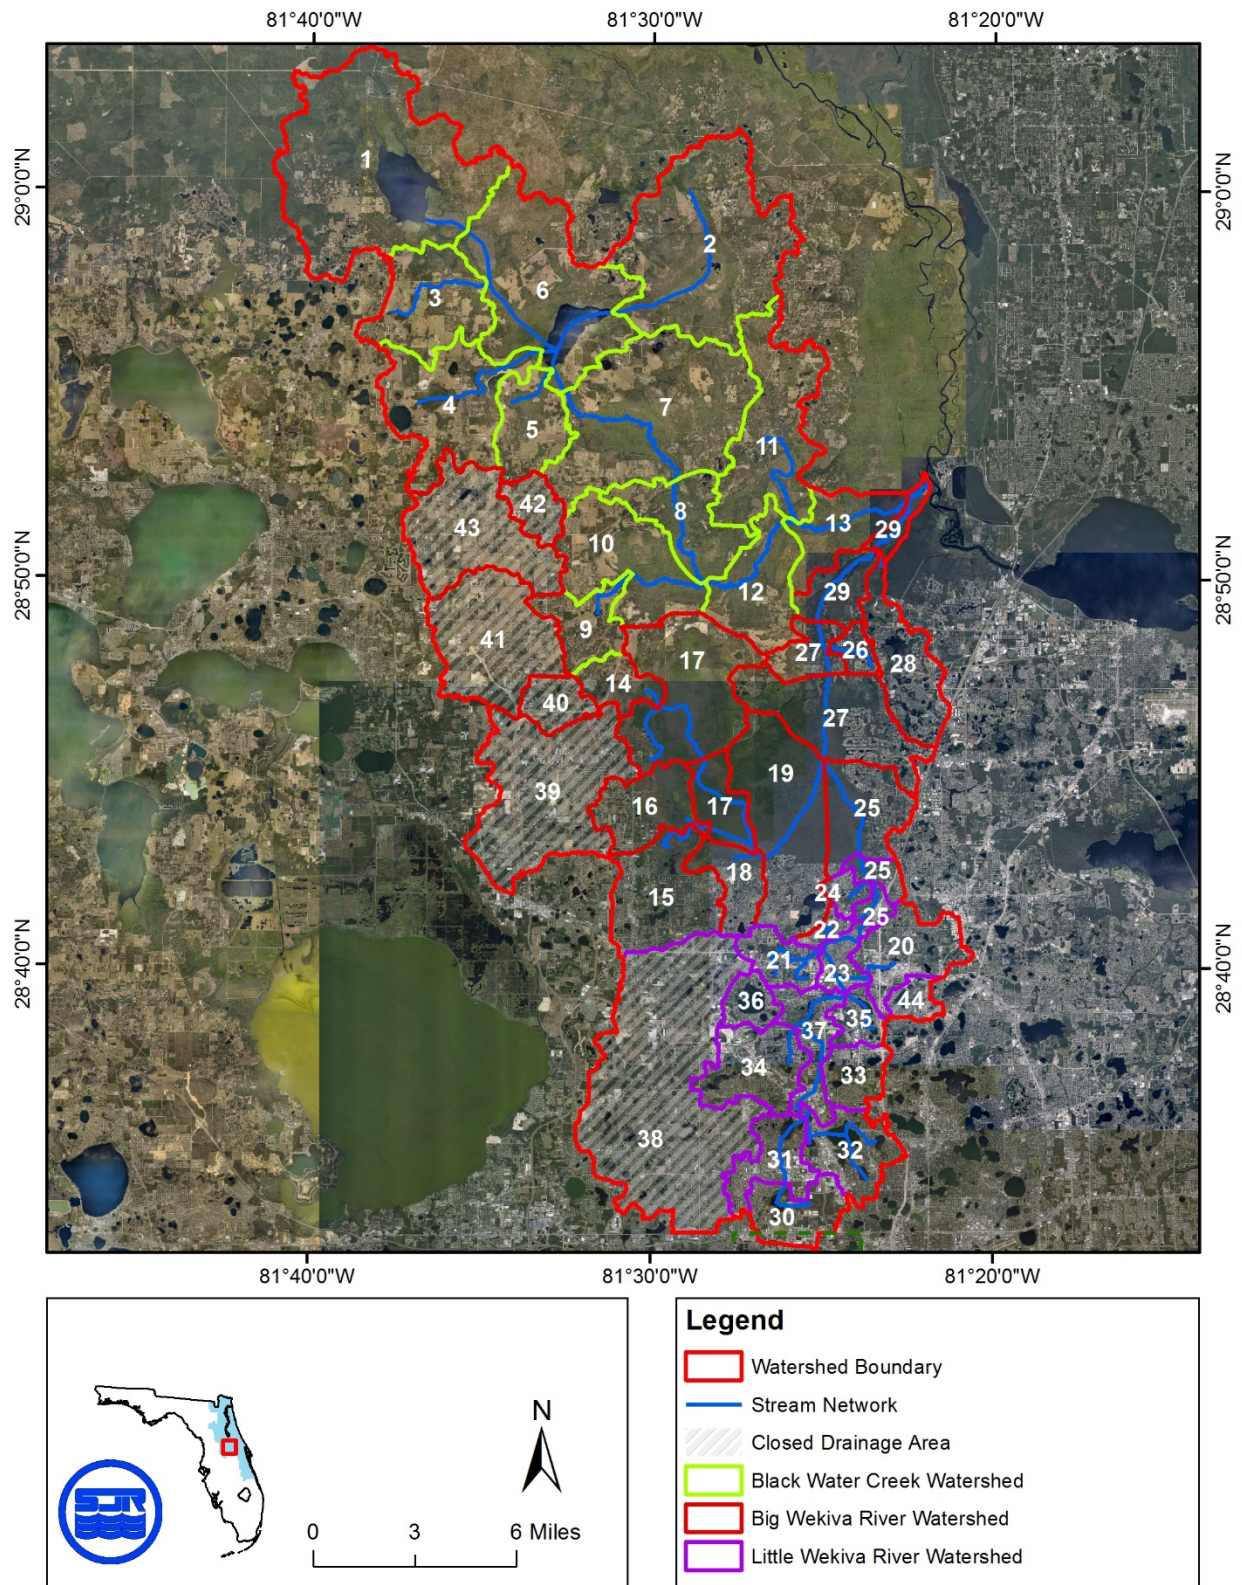

Figure 2 Sub-watersheds and major sub-basins of the Wekiva River watershed

2.2 LAND USE

The SJRWMD's 2009 land use and land cover map is used in this study. There are over 100 different land use classes within the Wekiva River watershed based on the Florida Land Use Classification Code System (FLUCCS). For modeling purposes, these land use classes are grouped into 13 major land uses, following the HSPF land use grouping method developed for the St. Johns River Water Supply Impact Study (Cera et al. 2012). Consolidation of the FLUCCS land use classes is mainly based on similarities in their hydrologic properties. Table 1 and Figure 3 show the distribution of these aggregated land uses in the Wekiva River watershed. The 2009 land use data was used in the model since the model simulation period was from 2003 to 2016. The 2009 land use data was compared with the most recently available 2014 land use data to determine if there are any significant changes in land use that could affect model calibration. The differences between 2009 and 2014 percent land use areas are listed in Table 1. This comparison revealed a very minor change in the land use occurred during this time window.

Table 1 Distribution of the HSPF land uses in the Wekiva River watershed

Land Use	Acreage	Percent of the Study Area	Difference in percent land use area between 2009 and 2014
Low Density Residential	17,893	7.4	0.17%
Medium Density Residential	29,249	12.2	0.32%
High Density Residential	5,971	2.5	0.57%
Industrial and Commercial	13,447	5.6	0.02%
Mining	366	0.2	0.19%
Open Land	2,275	0.9	-0.72%
Pasture	20,434	8.5	-0.32%
Agriculture General	12,563	5.2	-0.15%
Tree Crops	1,223	0.5	0.62%
Rangeland	13,670	5.7	-0.79%
Forest	58,388	24.3	-0.49%
Water	9,663	4.0	0.48%
Riparian Wetland	42,042	18.5	0.17%
Nonriparian Wetland	12,820	5.6	
Sum	240,403	100	-

To better represent the impact of wetlands on the drainage pattern in the Wekiva River watershed, the wetland land use category is split into two subgroups depending on whether wetlands are riparian (adjacent to streams or lakes) or non-riparian. Figure 4 shows the spatial distribution of riparian and non-riparian wetlands. The areas that drain to non-riparian wetlands are also shown in the map. The surface runoff from these areas are routed first to the non-riparian wetlands and then to the downstream streams or lakes. The baseflow from these areas are routed to the downstream streams or lakes directly.

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

The distribution of soil types in the Wekiva River watershed is depicted in Figure 6. The soil data was used as a reference to set the initial infiltration parameters (INFILT) used in hydrologic (HSPF) model calibration.

2.3 METEOROLOGICAL DATA

Daily rainfall data for four weather stations (Figure 7 and Table 2) were downloaded from NOAA. Missing rainfall data were filled using NEXRAD radar rainfall, available from SJRWMD. Daily rainfall totals for each station were disaggregated into an hourly time-series based on an hourly NEXRAD radar rainfall time-series. NEXRAD data from several National Weather Service (NWS) radar stations were calibrated with SJRWMD rain gauge data to provide a gauge-adjusted rainfall dataset. WDMUtil, the watershed data management tool for HSPF (USEPA, 2001), was used for rainfall disaggregation.

Potential evapotranspiration (PET) estimates were developed using the Hargreaves method (Hargreaves and Samani, 1985), with a monthly correction factor scaled to the Priestly-Taylor estimated evaporation (Priestley and Taylor, 1972), to standardize long periods of recorded input data to HSPF. PET and rainfall are summarized in Table 3 and annual rainfall is presented in Figure 8.

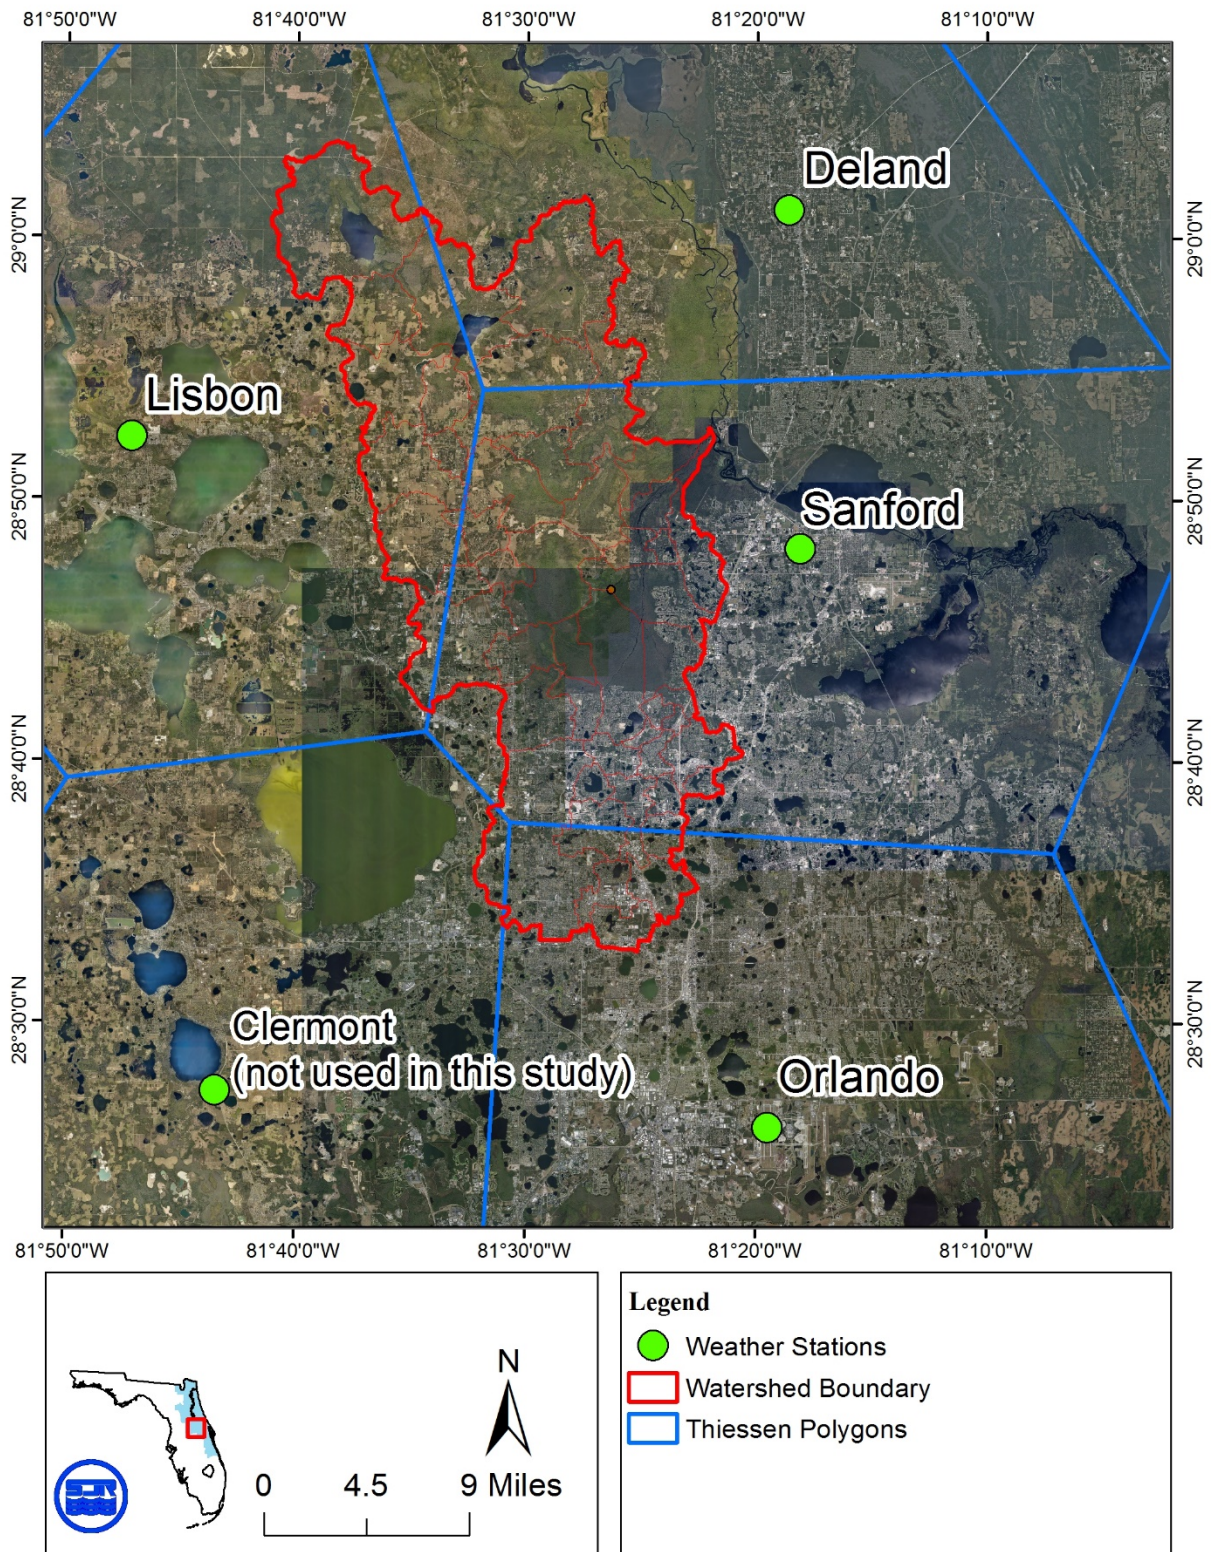

Table 2 Weather stations

Station Name	Station ID	Latitude	Longitude	Data Source	Period of Record

2.4 STREAM GAGES

Long-term daily flow and level data from eight sites along the main stems of Black Water Creek, the Little Wekiva River, and the Wekiva River were used in the model calibration (Figure 9 and Table 4). It should be noted that all the observed flow data were not measured directly, but were calculated based on the stage measurements using a rating curve, which describes the relationship between flows and stages. The rating curves were developed based on the field measurements of flows over a range of stages. The rating curves will continue to be updated periodically to reflect the channel morphological changes and to ensure the estimated flow is accurate for a given stage. Additionally, the Wekiva River near Apopka station was disabled between 2013-2015, so this period was excluded for the model calibration.

Table 4 List of stream gages

Station	ID	Source	Years	Data

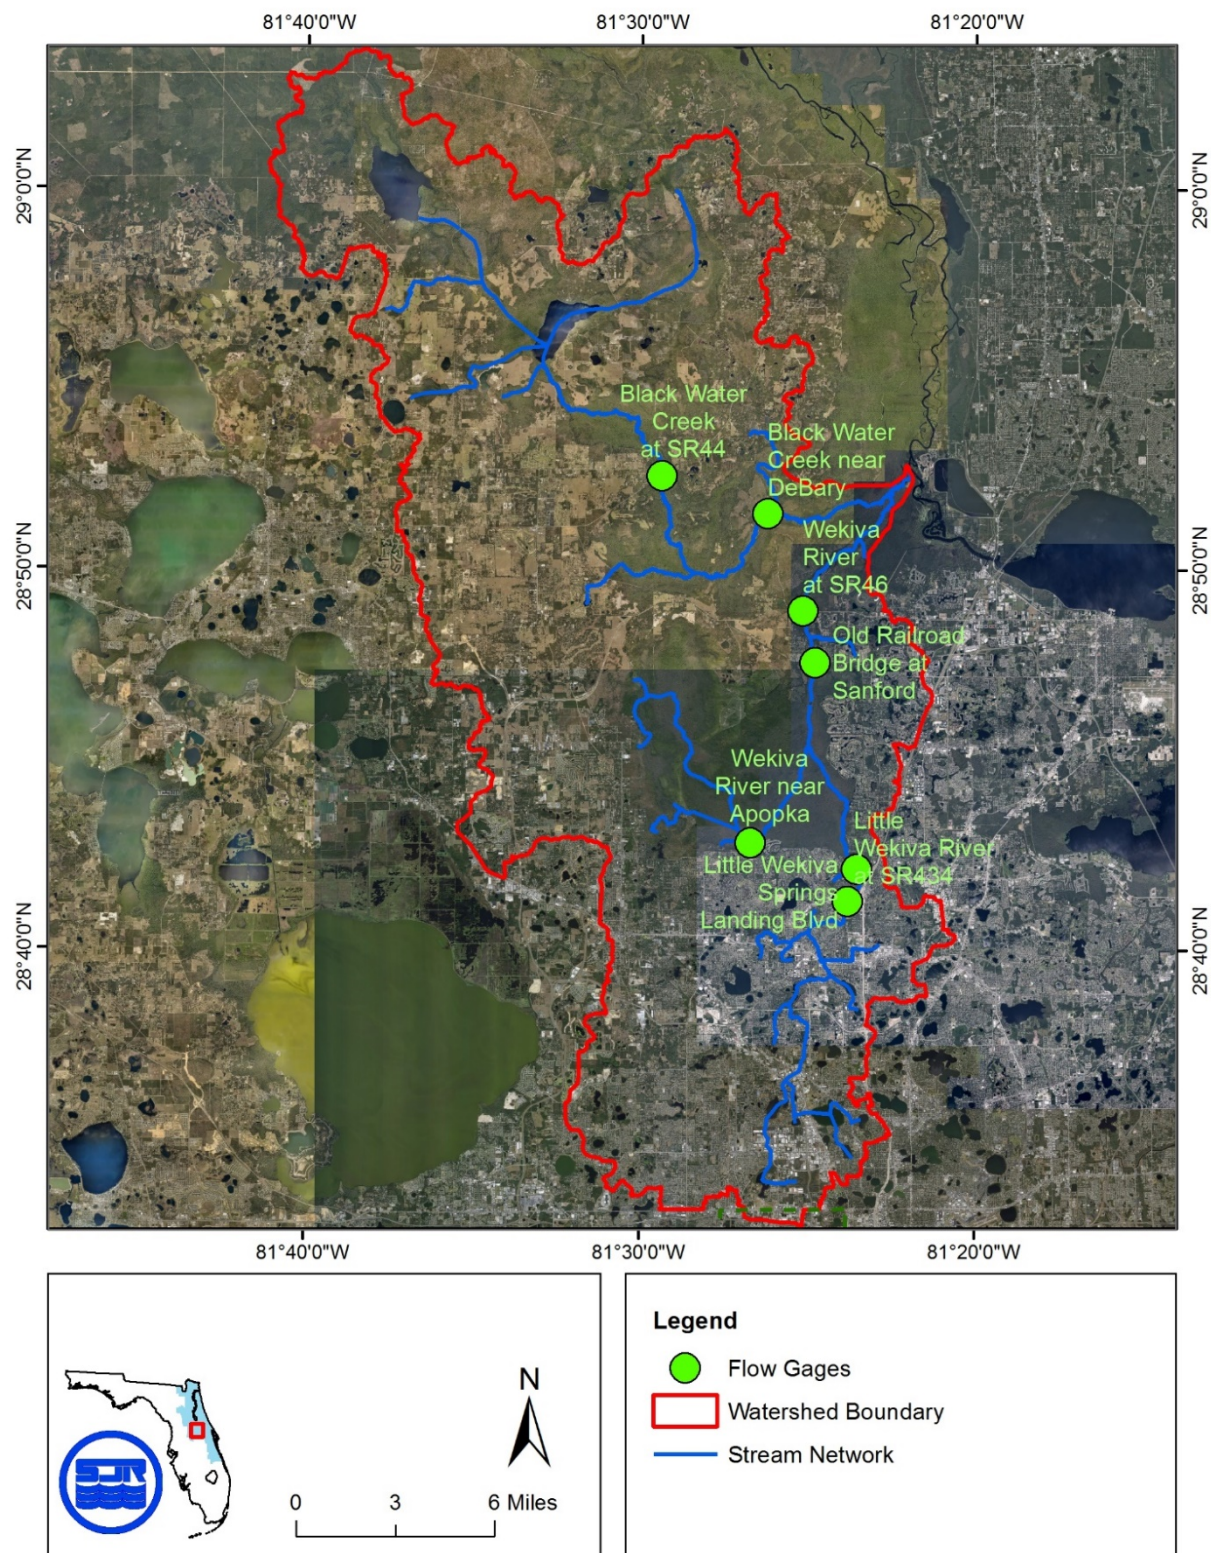

Figure 9 Map of Flow gage locations

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

Many factors, such as channel modifications, sediment deposition and erosion, vegetation encroachment, and herbicide application, can change river channel morphology and habitat. These changes subsequently alter the shape and roughness of the river channel, which affects the water velocity in the channel and over the floodplain. Given the complexity and interaction of these factors, it is difficult to pinpoint the main cause for the changing stage and discharge relationship over time. However, based on SJRWMD staff observations, in the last few years (after 2008) the main cause of the changing stage/discharge relationship appears to be the significant increase in vegetation in the Wekiva River (Figure 10 and 12). Further, Hurricane Irma (September 2017) caused erosion/scouring of the river bottom at the gage stations leading to a dramatic decrease in in-channel water levels (Figure 11). The dense in-channel vegetation reduces the river flow velocity and raises the in-channel water levels. This is further discussed in Section 4.1.2.

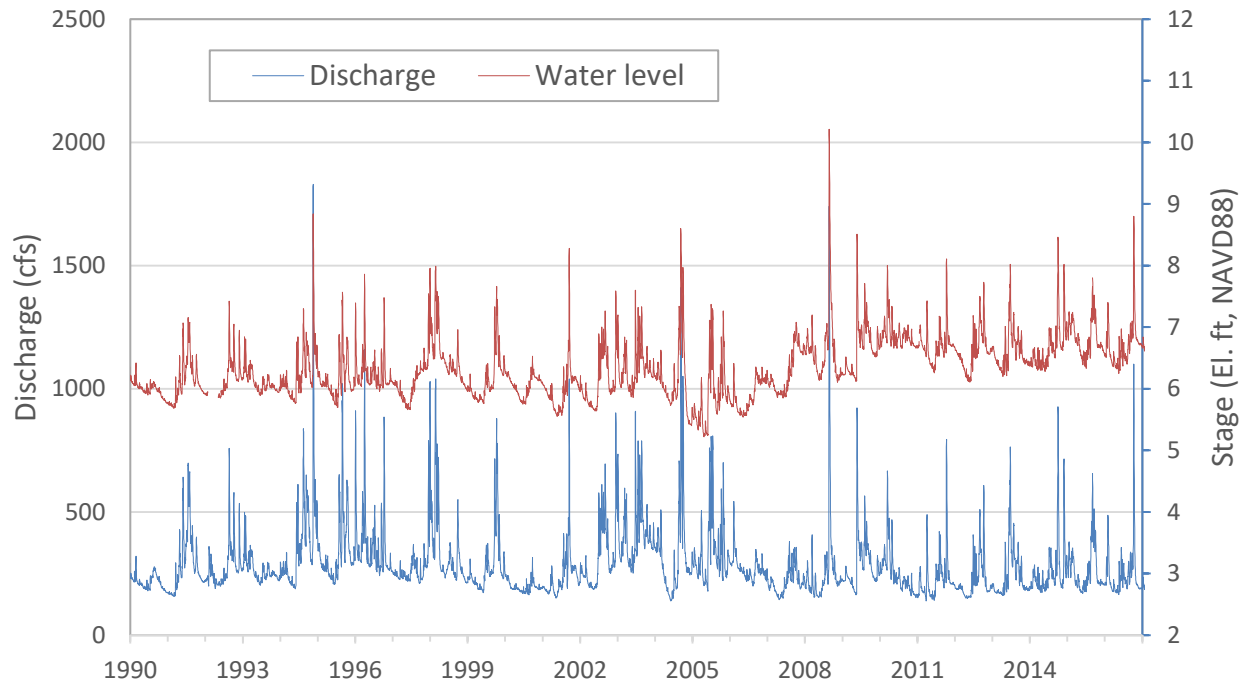

Figure 10 Flow and stage hydrographs for the Wekiva River at SR46

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

2.5 SPRINGS DISCHARGE

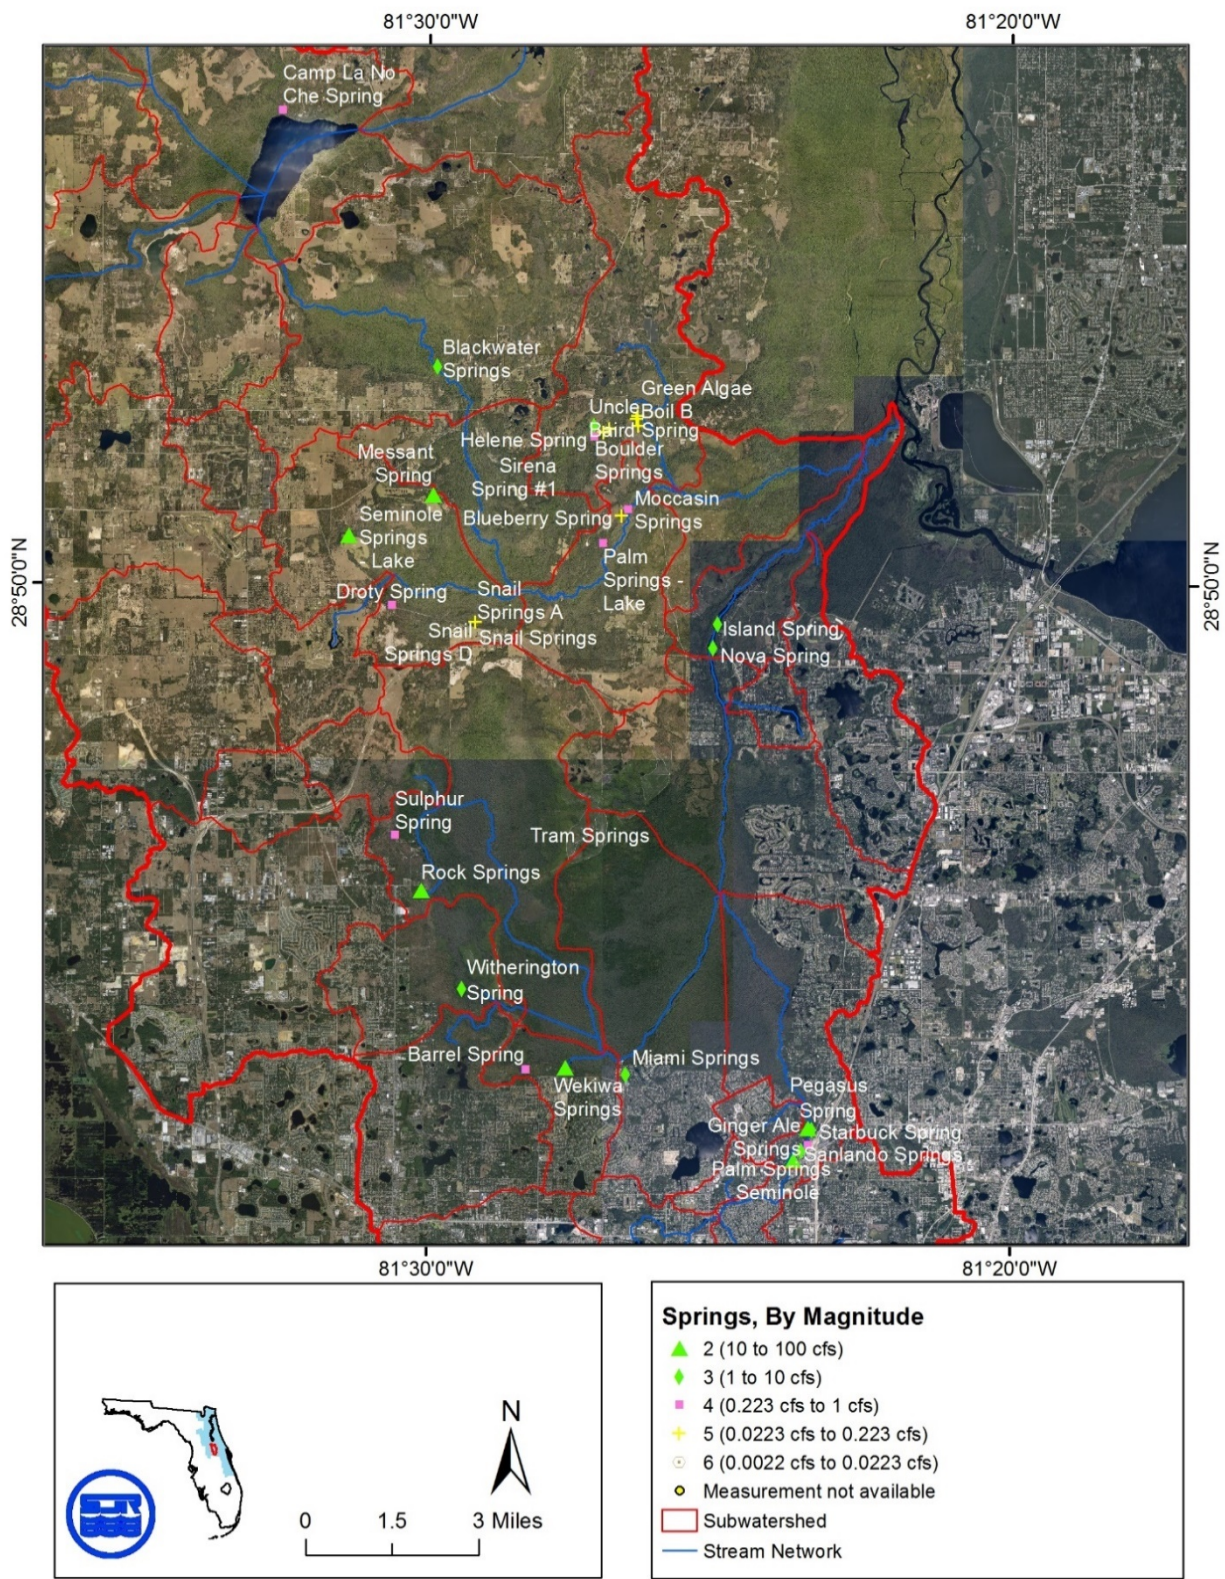

Springs are responsible for a substantial portion of the flow in the Wekiva River, especially in periods of low flow. For example, when river flow is less than 150 cfs, discharge from Wekiwa Springs alone could correspond to over 40% of the flow, and when all the springs are combined, this can contribute to 90% of the stream flow. Thirty-five springs were found in the Wekiva River watershed based on the SJRWMD database (Figure 13). Minor springs with negligible discharge that lacked measured data were not considered in the modeling. The 26 springs and Wekiwa Falls in the Wekiva River watershed that were incorporated into the model are listed in Table 5. Springs are classified by their average discharges. A first magnitude spring has a discharge of greater than 100 cfs; whereas, a fifth magnitude spring has a discharge of 0.0223 cfs to 0.223 cfs (Florida Geological Survey Bulletin No. 31). The average discharge and magnitude of each spring was evaluated between the years of 1970 through 2016. The method used in preparing the spring discharge datasets are described in Appendix A.

Table 5 Mean flows (1970-2016) and magnitudes for the springs with data in the Wekiva River watershed

Name	Average Discharge (cfs)	Spring Magnitude	Method/ N
Barrel Springs	0.24	4	Ratio / N=3
Blue Algae Boil Springs	0.13	5	Ratio / N=2
Boulder Springs	0.21	5	Ratio / N=3
Camp La No Che Springs	0.78	4	Ratio / N=3
Cedar Springs	0.03	5	Ratio / N=2

Witherington Springs	2.90	3	Ratio / Observed/ N=2
Palm Springs, Lake County	0.72	4	Ratio / N= 6

Seminole Springs	36.14	2	Ratio / N= 38
Wekiva Falls	18.59 (1995-2006) 13.17 (2007-2016)	2	ECFT & Ratio / N= 12

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

A combined approach was implemented to estimate discharges at Wekiva Falls, which showed a significant change in its amount of discharge in 2007. A significant reduction in discharge of Wekiva Falls was observed after a well was constructed near Wekiva Falls in 2007. Discharge simulation results using the East-Central Florida Transient (ECFT) Model (CFWI HAT 2014) for Wekiva Falls were used for the period of 1995-2007. The ratio method was applied to extend the timeseries to 2016. A multiplier calculated using recent Wekiva Falls discharge measurements was applied to the estimated timeseries by the ratio method from 2007 to 2016 to account for the reduction in discharge over that time-period (Figure 14 and Table 6).

Table 6 Recent Wekiva Falls Discharge Measurement

Date	Discharge (MGD)	Discharge (cfs)
1/5/2018	8.65	13.38
1/19/2018	8.85	13.69
2/19/2018	8.02	12.41

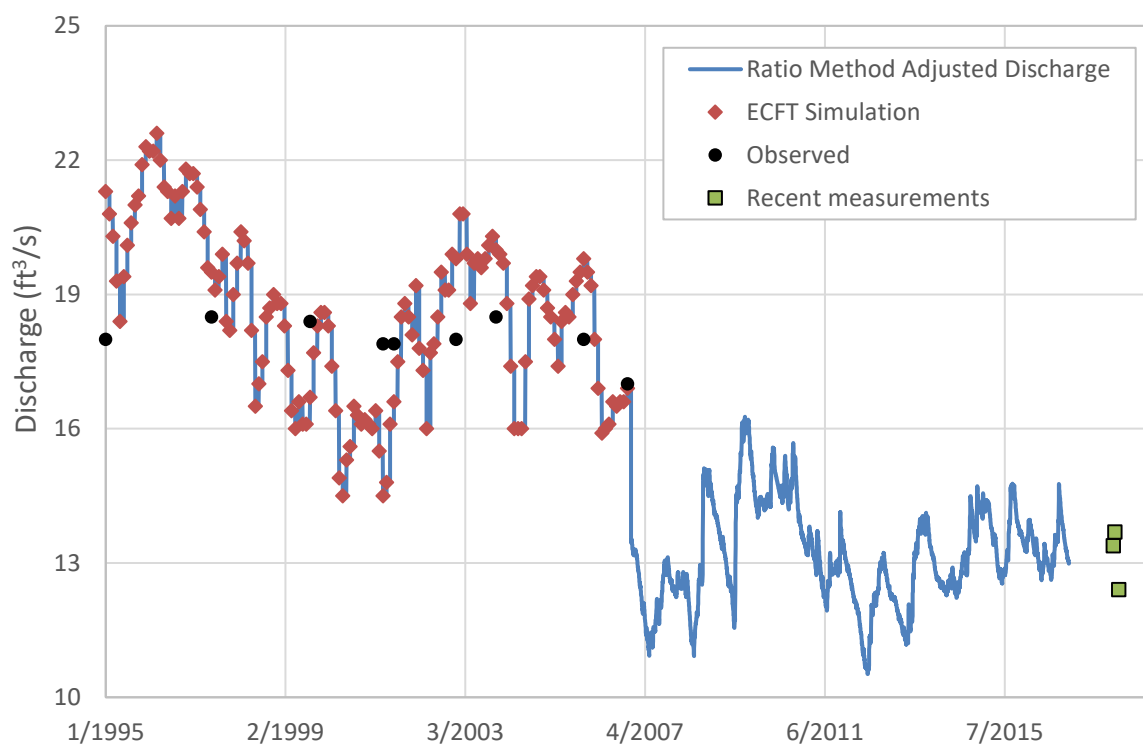

Figure 14 Adjusted Discharge at Wekiva Falls

2.6 POINT SOURCE DISCHARGE

Point source discharges, such as treated domestic wastewater and stormwater, occur throughout the Wekiva River watershed. FDEP identified 60 permitted point source discharge sites in the Wekiva River watershed (FDEP 2003). Of these point sources, two wastewater treatment facilities, Altamonte Springs/Swofford wastewater treatment facility (WWTF) and Wekiva Hunt Club WWTF, were identified to discharge treated wastewater effluent directly to the Wekiva or Little Wekiva Rivers (Table 7). These sites were modeled because they discharge at least 0.1

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

mgd and are permitted by NPDES to discharge into the Wekiva River. The remaining 58 facilities that were identified not to contribute or to minimally affect surface water were not modeled. The Altamonte Springs/Swofford WWTF outfall is located in sub-watershed 37, just upstream of the confluence between the Little Wekiva River and Spring Lake. The Wekiva Hunt Club WWTF discharges to Sweetwater Creek, which flows to the Wekiva River in sub-watershed 18. Monthly data for the two point source locations were prepared based on the discharge monitoring reports obtained from FDEP (<http://www.dep.state.fl.us/Water/wastewater/wce/edmr/index.htm>) and used in the hydrology model. Table 8 shows the average annual discharges from these two facilities.

Table 7 Point source locations used in the model

Name	FDEP ID #	Facility Type	NPDES Permit Volume (MGD)	Location
Altamonte Springs/Swofford	FL0033251	Domestic WWTF	12.5	950 Keller Rd, Altamonte Springs, FL 32714
Wekiva Hunt Club	FL0036251	Domestic WWTF	2.9	144 Ledbury Dr, Longwood, FL 32779

Table 8 Annual effluent discharges from Altamonte Springs/Swofford WWTF and Wekiva Hunt Club WWTF

Year	Altamonte Springs/Swofford WWTF FL0033251 (MGD)	Wekiva Hunt Club WWTF FL0036251 (MGD)
2000	1.14	1.58
2001	1.14	2.13
2002	1.15	2.13
2003	1.50	1.41

2.7 STREAM CROSS SECTION

Stream cross section data for the Wekiva River and its upstream locations were collected from various sources including 1990s survey data (A.R.Toussaint and Associates 1991; Post, Buckley, Schuh and Jernigan 1992; SJRWMD 1990), recent Wekiva River hydraulic modeling study (SJRWMD 2016), and SJRWMD surveying data to support MFLs assessments. Additionally, stream locations at Rock Springs Run and the Little Wekiva River were surveyed for this project (Figure 16-18 and Table 9).

The 1990s cross section data covers the entire Wekiva River including Rock Springs Run, Wekiwa Run and Little Wekiva River. The recent Wekiva River HEC-RAS modeling study used 20 cross sections on the Wekiva River downstream of the confluence with the Little Wekiva River. The recent SJRWMD environmental transects have been surveyed to collect biological and topographic information for MFLs analysis. The identified MFLs transects in the study area are asterisked in Table 9. When multiple cross sections were in the same or nearby location, the most recent cross section was selected as a representative transect for developing a hydraulic model; however, the SJRWMD MFLs environmental transects were all included in the hydraulic modeling. Elevations in the selected cross sections are relative to North American Vertical Datum -1988 (NAVD88).

A comparison of a few of the 1990s cross section data with recently surveyed cross sections found that the cross sections at ROK2 and ROK3 were comparable in terms of bottom elevation, stream width and bank, and general shape of cross section (Figure 15). This indicated that the 1990s cross section measurements could be used for the model development.

3. HYDROLOGIC MODEL DEVELOPMENT FOR WEKIVA RIVER WATERSHED

3.1 HSPF MODEL SETUP

An existing HSPF model for the Wekiva River watershed (SJRWMD, 2016) was updated for this study. The model domain spans the Rock Springs Run, Little Wekiva River, Black Water Creek, Wekiwa Run, and the Wekiva River watersheds. The watershed model simulation period was extended to the period of 2003 to 2016. The spring discharge dataset used in the previous model was updated based on measured data. The model was calibrated using the extended simulation period (2003-2016) and the updated data. Detailed model performance evaluation follows in the next section.

3.1.1 Model segmentation

A watershed and its stream network are characterized in HSPF by various pervious land segments (PERLND), impervious land segments (IMPLND), and reach segments (RCHRES) based on sub-watershed delineation, land uses, and the ratio of perviousness and imperviousness for each land use. As described in section 2.2, the land uses in the Wekiva River watershed are grouped into 13 categories. These land uses are further divided into pervious and impervious fractions. The pervious portion of a land use in a sub-watershed is represented as a PERLND, and the impervious portion of a land use in a sub-watershed is represented as an IMPLND. Among 13 land uses, four urban land uses (Low density residential, medium density residential, high density residential, and industrial/commercial) are assumed to have impervious areas. The impervious percentages for these land uses are 5, 10, 35 and 50, respectively. The remaining land uses are assumed to be 100% pervious (Bicknell et al., 2001).

For modeling purposes, the stream network in a sub-watershed is grouped together and represented as a RCHRES. A RCHRES could be either a free-flowing stream or a lake. A series of reach segments connects upstream sub-watersheds to downstream sub-watersheds. Runoff is routed through the reach segments. The geometric and hydraulic properties of a RCHRES are represented in HSPF by a piecewise-linear function table called FTABLE, which describes the relationships between stage, surface area, volume, and discharge for the reach segment (Bicknell et al., 2001). The FTABLEs are mainly derived from the modeling results of the ICPR models developed by CDM (2005) and the SJRWMD's HEC-RAS model, which is described in the next chapter. In addition, cross section survey data, lake bathymetry, observed stage and discharge relationships are used for FTABLE development. In total, 44 reaches are represented in the Wekiva River watershed HSPF model.

The reach segment draining a sub-watershed receives runoff from the land segments in that sub-watershed. For the area not drained by non-riparian wetlands, runoff is delivered to the reach segment directly. However, for the area drained by non-riparian wetlands (see Figure 4), surface runoff and interflow are first delivered to non-riparian wetlands, and then the outflows are delivered to the reach segment. The non-riparian wetlands are modeled by surface FTABLEs in HSPF to represent the high-water table and storage effects in non-riparian wetlands. The impacts of non-riparian wetlands on baseflow runoff are assumed to be negligible. Consequently,

the baseflow originating from the non-riparian wetland drainage areas is routed to receiving reach segment directly.

3.1.2 HSPF modules

HSPF has a modular structure, in which the simulation of PERLND, IMPLND and RCHRES is handled by the PERLND module, the IMPLND module, and the RCHRES module, respectively. Each of these modules includes a variety of submodules to perform different tasks. Hydrologic simulation for PERLND and IMPLND is performed in the PWATER submodule and the IWATER submodule. The simulated hydrologic processes for a PERLND are interception, infiltration, evapotranspiration, runoff, and deep percolation. The simulated processes for an IMPLND are similar to those for a PERLND, except there are no infiltration and subsequent subsurface processes. Hydraulic behaviors in a RCHRES are simulated in the HYDR submodule. Detailed description of these submodules can be found in Bicknell et al. (2001).

During a simulation run, the riparian wetland PERLND areas will change as the RCHRES surface expands and contracts. The HSPF Special Actions module is used to account for variable PERLND and RCHRES surface areas. Different areas for water and wetlands are used so that both the PERLND and RCHRES section in a sub-watershed would not use the same area at the same time. For most sub-watersheds, the average RCHRES area can be subtracted from the PERLND water and wetland area for each sub-watershed. This would cause some double counting of rainfall and evaporation when water levels are high and some undercounting when water levels are low. As long as this area is small, this error is considered insignificant to the overall model. When the variable area within the RCHRES becomes large, however the error becomes significant. The Special Actions for variables PERLND and RCHRES calculate the current RCHRES area and subtract it from the total water and wetland area for the sub-watershed. Then the model uses this area as a wetland PERLND in the modeled sub-watershed (Bicknell et al., 2001). This action is applied to every sub-watershed in this study.

3.1.3 Model calibration

Calibration of HSPF models involves an iterative adjustment of model parameters until model simulations closely match the observed flow data. To assist the calibration process, an automatic parameter estimation tool called PEST (Doherty 2004) is used. PEST uses a nonlinear optimization approach to explore the parameter space defined by the modeler and find the best parameter set for the specified objective function. Various statistic measures are used by PEST to minimize the differences between the predicted and observed flows in terms of mass balance, low flow recession, flow distribution, and seasonal distribution. The objective function typically includes multiple weighted statistical measures, such as mean and percentiles, to evaluate the statistical characteristics of model simulations and observations. The modeler considers adjusting these statistical measures and their weights during calibration to get the best match between model simulations and observed data. The statistical measures and its relative contributions to the objective function used in the calibration is documented in Table 10.

A variety of HSPF hydrologic parameters relating to watershed storage, infiltration, evaporation, and deep percolation are adjusted in the hydrologic calibration process to match the observed flows at USGS flow stations over the calibration period from 2003 to 2016. The extents of

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

adjustment for these hydrologic parameters are defined by the HSPF Common Logic developed for the St. Johns River Water Supply Impact Study (Cera et al. 2012). This HSPF Common Logic was derived from an evaluation of the possible range of model parameters for Florida's unique hydrology, extensive SJRWMD experience, and the parameter ranges common in other parts of the world (USEPA 2000). The calibrated parameter values are provided in the Appendix B.

Table 10 Statistical measures and its weights to the objective function for PEST calibration.

Sub models	Series Name	Description	Weight
Black Water Creek	Qmea3, Qmea7	Sum of differences between simulation and observation in daily flow time-series at SR44 and Near Debary stations	1

3.2 MODEL PERFORMANCE EVALUATION

In this study, the HSPF model results were evaluated with statistical measures of coefficient of determination (R^2), Nash-Sutcliffe efficiency (NSE), percent bias (PBIAS), and RMSE-observations standard deviation ratio (RSR) as well as visual comparison of observed and simulated flow time series and flow duration curves. Table 11 is a guide for assessing the performance of hydrologic model.

Table 11 Hydrologic model performance guide

Statistics	Period	Very Good	Good	Fair	Poor	Ref.
R^{2*}	Daily	$0.80 < R^2 \leq 1$	$0.70 < R^2 \leq 0.80$	$0.60 < R^2 \leq 0.70$	$R^2 \leq 0.60$	Duda et al, 2012
R^2	Monthly	$0.86 < R^2 \leq 1$	$0.75 < R^2 \leq 0.86$	$0.65 < R^2 \leq 0.75$	$R^2 \leq 0.65$	Duda et al, 2012
NSE	Monthly	$0.75 < NSE \leq 1$	$0.65 < NSE \leq 0.75$	$0.50 < NSE \leq 0.65$	$NSE \leq 0.50$	Moriasi, et al, 2007
PBIAS	Monthly	$PBIAS < \pm 10$	$\pm 10 \leq PBIAS < \pm 15$	$\pm 15 \leq PBIAS < \pm 25$	$PBIAS \geq \pm 25$	Moriasi, et al, 2007
RSR	Monthly	$0 \leq RSR \leq 0.5$	$0.5 < RSR \leq 0.6$	$0.6 < RSR \leq 0.7$	$RSR > 0.7$	Moriasi, et al, 2007

* Performance criteria ranges estimated from Figure 4 in Duda et al.

R^2 describes the degree of collinearity between simulated and measured flow (Nagelkerke, 1991), ranging from 0 to 1, where N is the total number of flow data; Q_{obs} is observed flow; Q_{sim} is simulated flow; and the over bar denotes the mean for the entire evaluation time period. R^2 of 1 means a perfect linear relationship between two variables, while an R^2 of zero represents no linear relationship.

$$R^2 = \left(\frac{\sum_{i=1}^N (Q_{obs,i} - \bar{Q}_{obs})(Q_{sim,i} - \bar{Q}_{sim})}{[\sum_{i=1}^N (Q_{obs,i} - \bar{Q}_{obs})^2]^{0.5} [\sum_{i=1}^N (Q_{sim,i} - \bar{Q}_{sim})^2]^{0.5}} \right)^2$$

NSE is a normalized value that assesses the relative magnitude of the residual variance, ranging from minus infinity to 1 (Nash, J.E. et al., 1970). NSE values greater than zero imply that the model predictions are more accurate than the average of the observed data, and a $NSE = 1$ indicates the model predictions completely match observed data.

$$NSE = 1 - \frac{\sum_{i=1}^N (Q_{obs,i} - Q_{sim,i})^2}{\sum_{i=1}^N (Q_{obs,i} - \bar{Q}_{obs})^2}$$

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

PBIAS represents the overall agreement between two variables. A PBIAS of zero means there is no overall bias in the simulated output of interest compared to the observed data. Positive and negative PBIAS values indicate over-estimation and under-estimation bias of the model, respectively (Gupta, H.V. et al, 1999).

$$PBIAS = \frac{\sum_{i=1}^N (Q_{sim,i} - Q_{obs,i}) \times 100}{\sum_{i=1}^N (Q_{obs,i})}$$

RSR uses the fraction of RMSE and STDEV_{obs} to measure model performance. Results can vary from 0 to a large positive value. A lower RSR value indicates better model performance.

$$RSR = \frac{RMSE}{STDEV_{obs}} = \frac{\sqrt{\sum_{i=1}^N (Q_{obs,i} - Q_{sim,i})^2}}{\sqrt{\sum_{i=1}^N (Q_{obs,i} - \bar{Q}_{obs})^2}}$$

Table 12 presents the statistical measures to quantify the performance of the hydrologic model at the 7 discharge stations in the Wekiva River watershed.

Table 12 Results of performance analysis

	NSE	0.65	0.59	0.68	0.75	0.49	0.69	0.66
	RSR	0.60	0.64	0.57	0.50	0.71	0.56	0.59
Monthly	RMSE	38.52	53.31	14.88	22.98	22.96	49.78	55.93
	R ²	0.74	0.72	0.80	0.82	0.52	0.77	0.71
	PBIAS %	-5.4	-0.60	-3.30	-7.60	-0.10	7.00	1.70
	NSE	0.70	0.66	0.79	0.79	0.42	0.71	0.69
	RSR	0.55	0.58	0.45	0.46	0.76	0.54	0.56

Hydrographs of monthly and daily observed discharge data are overlaid with the model simulation results at each of the calibration sites. A flow duration curve for each site illustrates the probability of exceedance of daily average flow, comparing both simulated and observed data. A scatterplot of the monthly observed discharge versus the monthly simulated discharge is also provided to assess the performance of the model (Figures 19-25).

The calculated statistics in Table 12 indicate that the model performed well. The model simulation for 6 of the sites was considered fair to very good based on NSE values. Excluding Near Apopka, monthly NSE values were calculated in the range of 0.66 to 0.79, while monthly PBIAS ranged from -7.6% to 7.0%. The relatively lower NSE value for the Near Apopka site could be because the rainfall dataset didn't capture some of the storm events in that discharge area (see Figure 23a and 23b) and the site was disabled from 2012-2016, so no data is available for that time. Further, the flow at this station could have been highly impacted by some surrounding urban development activities that could not be accounted for temporally. Nonetheless, since RMSE for the Near Apopka site is lower than most of the sites and simulated flow duration curve matches the observed flow duration curve very well, model performance at this site is still reasonable (see Figure 23d).

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

The average annual water budget was calculated by sub-basin, based on the model simulation result for the period of 2003-2016 (Table 13). The water budget calculations have also been broken down by land use in Appendix B. Rainfall (51.4 in/ac/yr) and spring flow (11.5 in/ac/yr) were the two major inputs for the Wekiva River watershed. This was predominately offset by evapotranspiration (63%); however, discharge to the St. Johns River (32%) and groundwater recharge (5%) were also significant outflows. The main Wekiva River and Black Water Creek watersheds have around 40 in/ac/yr of ET, while the Little Wekiva River watershed presents 33 in/ac/yr. The ET value in the Little Wekiva River watershed is lower than the other sub-watersheds because of its higher percentage of impervious area. The recharge rate (8.8 in/ac/yr) in the Little Wekiva River watershed is higher than the other watersheds (2 in/ac/yr), due to its average topographic elevation and sandy soil characteristics. The recharged water contributes to springs, that are mostly found in the low-lying region near streams.

Table 13 Results of performance analysis

Watershed	Rainfall (in/ac/yr)	ET (in/ac/yr)	Recharge (in/ac/yr)	Spring (in/ac/yr)	Upstream and PS (in/ac/yr)	Outflow (in/ac/yr)
Black Water Creek	50.6	41.8	1.9	4.6	0.0	12.3
Little Wekiva River	51.4	33.4	8.8	9.8	0.2	20.3
Main Wekiva River	53.0	40.5	2.2	26.9	39.7	78.0
Total	51.4	39.9	3.2	11.5	-	20.6

4. HYDRAULIC MODEL DEVELOPMENT FOR THE WEKIVA RIVER AND ASSOCIATED TRIBUTARIES

4.1 HEC-RAS MODEL DEVELOPMENT

4.1.1 Model domain

The HEC-RAS model domain includes Rock Springs Run, Wekiwa Springs Run, the segment of Little Wekiva River downstream of the SR464 bridge, and the segment of Wekiva River from its junction with Rock Springs Run to the Lower Wekiva River gage (Figure 26). In total, 72 cross sections based on the availability at the time of model development were used to represent the study area in the model. Density of cross sections varied by streams. For example, 38 transects over 13.3 miles of the Wekiva River were used in the model, while 5.9 miles of the Little Wekiva River portion were represented with 8 cross sections. Upstream waters of the Wekiva River above the confluence with the Little Wekiva River were set up with relatively less cross section data compared to the Wekiva River downstream from the Little Wekiva River confluence. When the distance between the upstream and downstream cross sections was too large, such as XS1 and Lower Wekiva, interpolated cross sections were added to reduce model instability during the model simulation.

Water levels simulated by the model are most accurate at or near surveyed cross-sections; therefore, simulated water levels further from surveyed cross-sections should be used cautiously. The vertical datum used in the model construction is feet-NAVD88.

As discussed in Section 2.4, due to streambed condition change, observed stages at low flow conditions in the Wekiva River were significantly increased after 2008, and the pattern was consistent through 2016. Thus, instead of using the HSPF model simulation period (2003-2016), the period from 2008 through 2016 was selected to develop flows and stages for HEC-RAS model simulations.

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLs EVALUATIONS

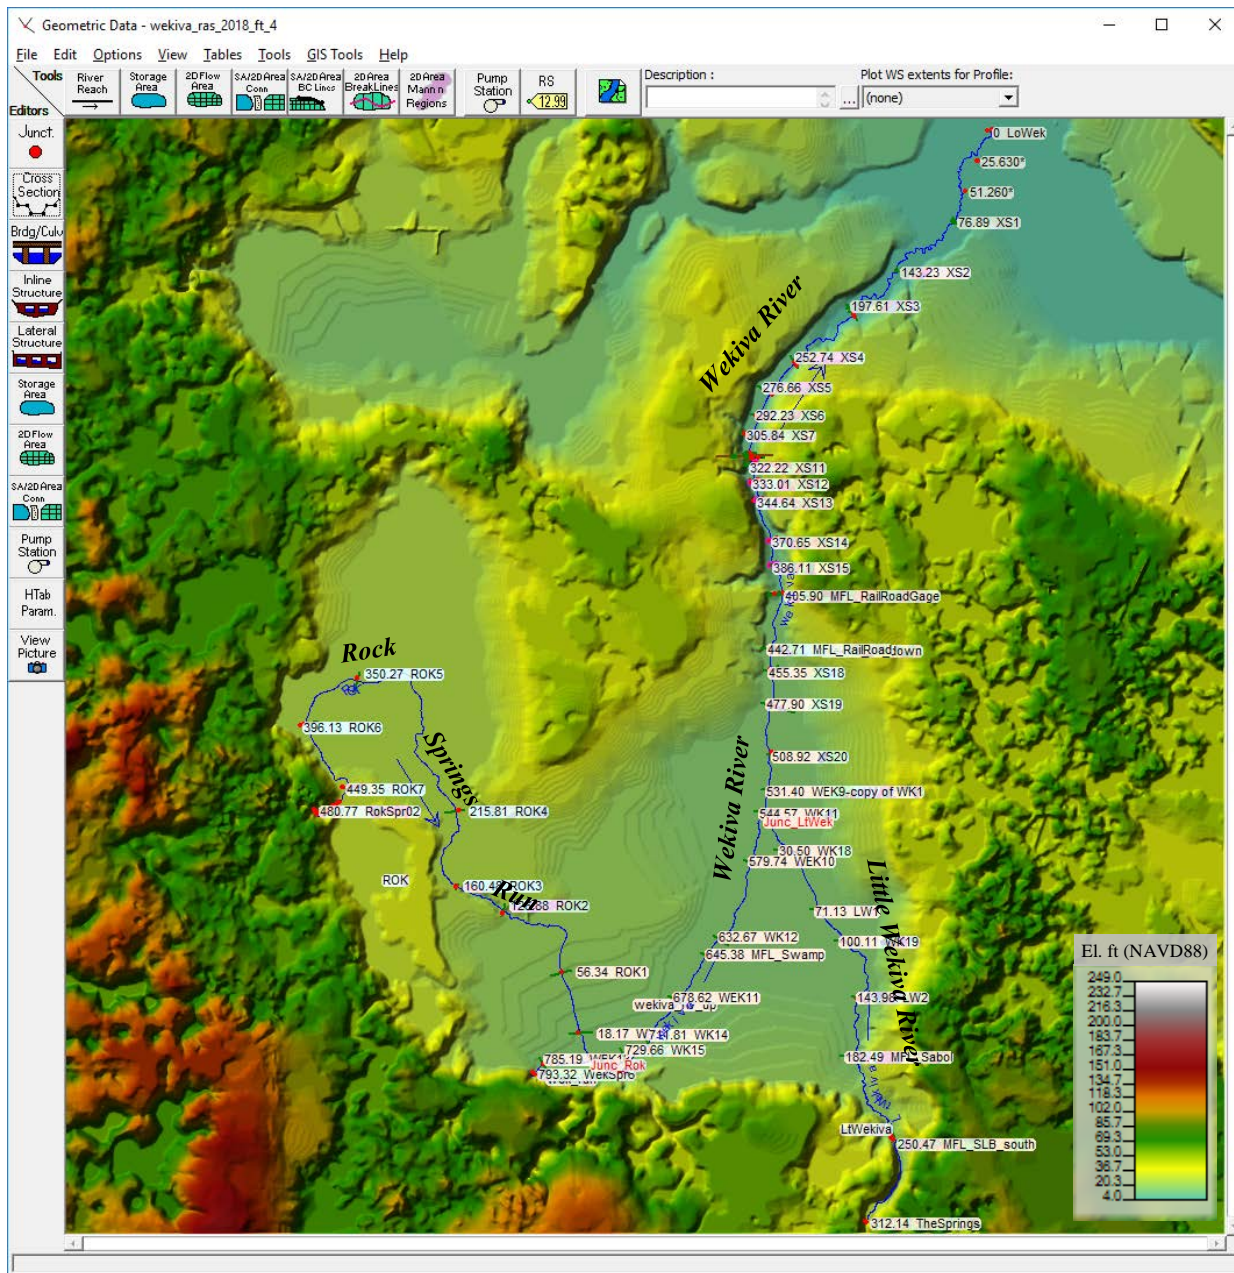

Figure 26 Geometric data view of the HEC-RAS model for Wekiva River

4.1.2 Manning's n

Floodplain and instream vegetation significantly impact both stage and flow. Previous studies showed that in a highly vegetated channel, Manning's n is generally decreased as stream depth increases (Kadlec and Wallace, 2009 and Wu et al., 1999). Highly vegetated stream segments are often encountered in the Wekiva River and upstream segments (Figure 27-31); friction from this streambed vegetation varies by flow or water level and contributes to water level increase.

Figure 27 Vegetated stream near ROK2. The photo was taken by J. Mace on 2/27/2018. The white tape ruler line found near the bottom of the picture is for surveying the stream cross section and is perpendicular to the stream direction.

Figure 31 Black Water Creek near SR44. The photo was taken by J. Mace on 10/21/2010.

HEC-RAS model provides options for varying Manning's n by flow or depth. A preliminary analysis, based on the period of 2008-2016, was conducted to calculate Manning's n at SR 46; its results showed more consistent relationship between Manning's n and flow (Figure 32). This cleaner relationship is because the base level changes from the gage are accounted for implicitly in the model. Therefore, Manning's n was varied with respect to flow in the HEC-RAS model to simulate low to high flow regimes for both steady and unsteady simulation. In the steady state simulation, the "Vertical Variation in Manning's n Values" option under cross section data editor was used to vary Manning's n , while the "flow roughness factors" option was implemented during the unsteady state simulation.

(b) Varied Manning's n by flow

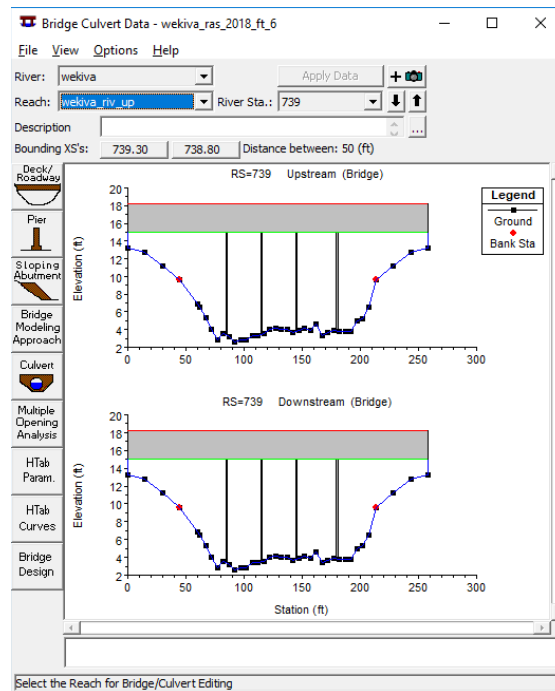

Figure 32 Calculated Manning's n values by different water level and discharge at the SR46

4.1.3 Bridges

The Wekiva River bridges at SR46 and at the end of Miami Springs Drive were included in the HEC-RAS model (Figure 33). The survey of the bridge at SR46, such as pier and deck geometric data, were derived from a previous HEC-RAS modeling work (Jia, Y. and Suarez, G., 2016) and it was verified through field observation. The bridge geometry located at the end of the Miami Springs Drive, was collected from a field trip in 2018.

4.2 STEADY STATE SIMULATION AND CALIBRATION

4.2.1 Boundary conditions for steady state simulation

Observed water level data at the Lower Wekiva gage (located 0.9 miles from the Wekiva River mouth) were used as a downstream boundary condition, while discharge data at Rock Springs, Wekiwa Springs and the Little Wekiva River at SR 434 gaging stations were applied to upstream boundary conditions (Figure 34).

Table 14 Summary of boundary conditions and flow change locations for steady simulation in the HEC-RAS model

Streams	River Station	Boundary Condition Type	Description
Little Wekiva River	312.14	Upstream boundary condition	SR434 (RCH23*)

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLs EVALUATIONS

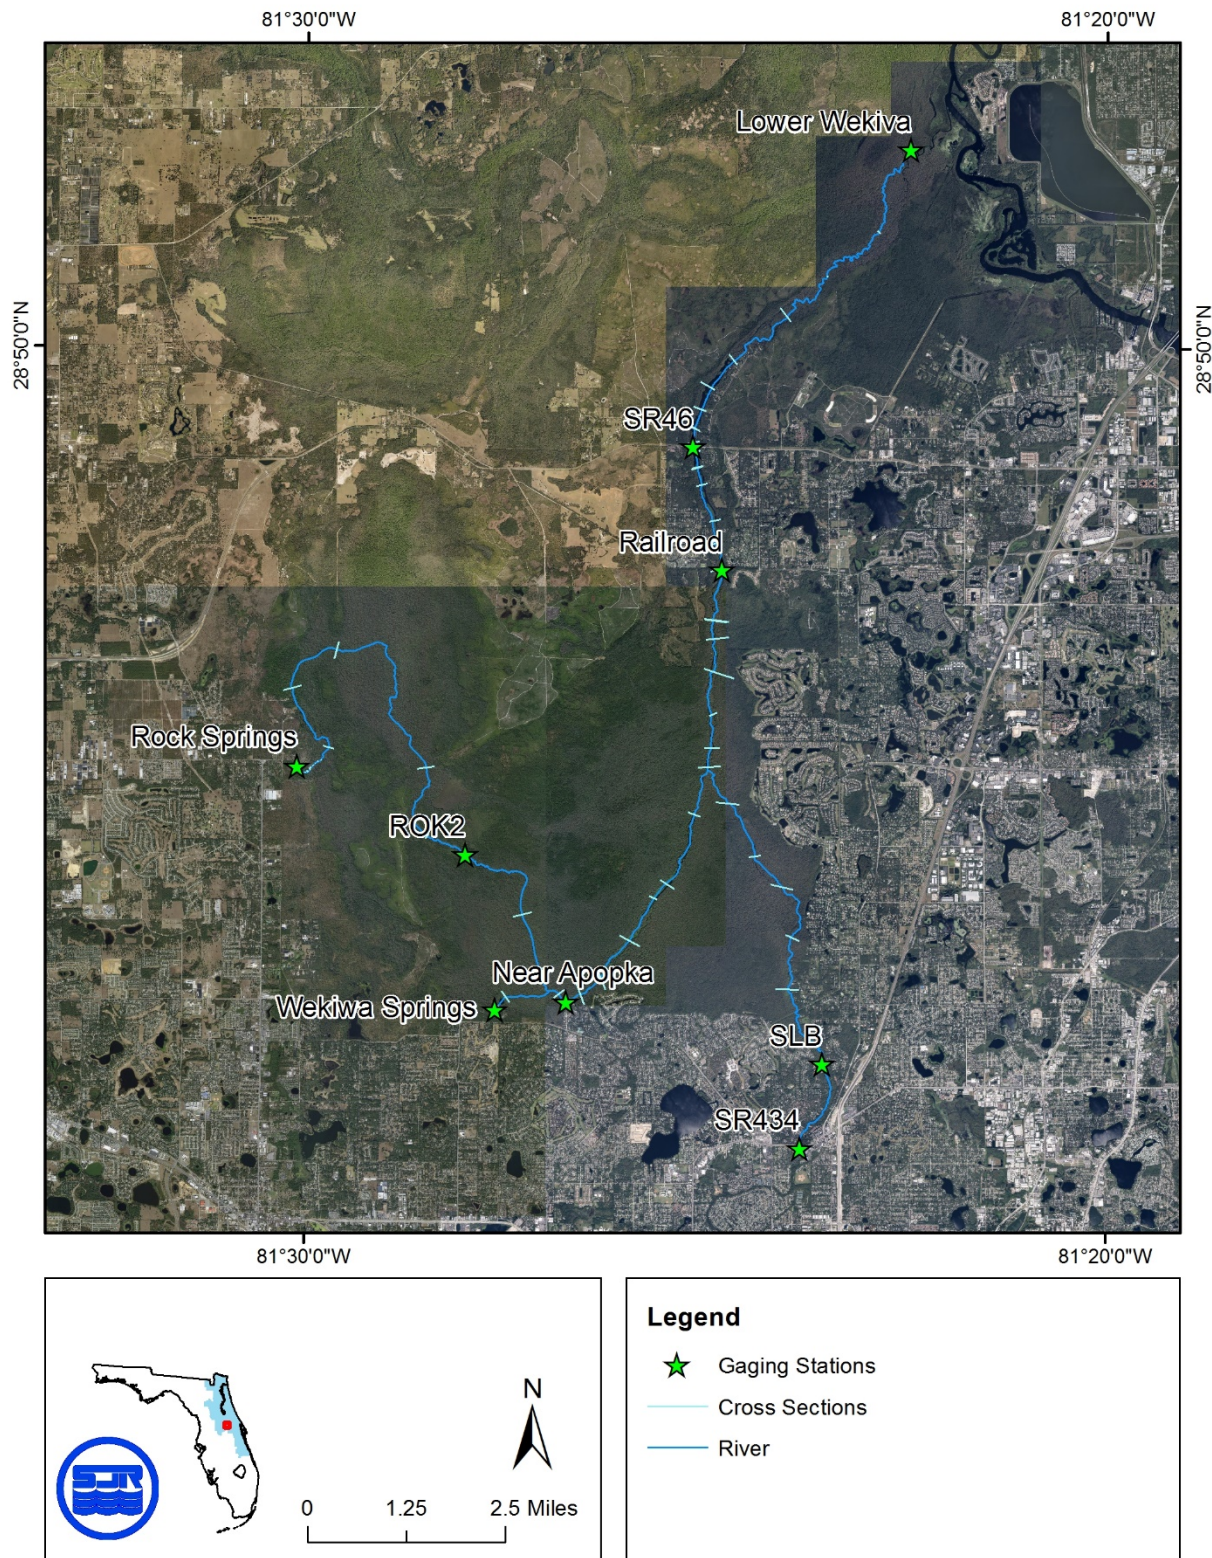

Figure 34 Locations of gaging stations and cross sections for the HEC-RAS model simulation

4.2.2 Channel flow profiles

For the steady state simulation in HEC-RAS modeling, channel flow profile inputs are required to ensure that the model is applicable at the given flow regime. Instead of developing synthetic smooth flow profiles as traditionally done, channel flow profiles were formulated with daily observed flow data between 2008 and 2016. This approach provides flow conditions consistent with the observed river hydrologic condition, which, therefore produced a better calibrated model. Efforts have been made to select days that capture low to high flow conditions in Wekiva River. Thirteen flow profiles were selected based on flow exceedance analysis at SR46 (Figure 35), and consisted of 3 low flow (<10%), 2 medium flow and 8 high flow (>90%) conditions (Table 15).

Figure 35 Flow exceedance for the Wekiva River at SR46 and selected discharge profile

Table 15 Selected flow profile for steady state simulation for Wekiva River

Profile	Date	Flow at SR46	Exceedance Probability
PF1	4/17/2012	150	99.4
PF2	5/14/2012	155	97.7
PF3	4/9/2013	164	93.5
PF4	5/14/2013	196	69.0
PF5	2/15/2016	225	46.0
PF6	8/27/2012	407	6.3
PF7	9/9/2015	467	4.1
PF8	12/4/2014	479	3.7
PF9	9/30/2014	665	1.4

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

PF10	10/1/2014	797	0.8
PF11	5/22/2009	922	0.4
PF12	10/2/2014	927	0.4
PF13	8/23/2008	1740	0.0

Along the model domain, 17 flow-change locations were selected based on tributaries and contributing drainage areas, as defined in the HSPF model (Figure 36). Table 16 shows the prepared discharge profiles at the given flow change locations. Discharge data included in the model was obtained from the gages of the Little Wekiva River at SR434, Rock Springs, Wekiwa Springs and the Wekiva River at SR46. When observed data were not available at flow-change locations, HSPF modeling results were used with adjustment factors. These factors were derived from the relationship with downstream observed flows to estimate the channel flow profiles at the given flow-change location.

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

4.2.3 Steady state simulation results

The HEC-RAS model was calibrated by adjusting the Manning's n value to minimize surface water level differences between the observations and simulations at the eight water level gaging stations. The criterion for the calibration was 0.5 ft in discrepancy between the simulated and observed stages. All simulated profiles at the eight gages were within the criterion with a few exceptions, and showed a strong correlation with observed stages (Figures 37-38). The most downstream gage, Wekiva River at SR46, showed the least difference ranging from -0.26 to 0.01 ft. Only at two stations in the Little Wekiva River at SR434 and Rock Springs Run the model did not meet the criterion (asterisked values in Table 17). The model simulations are still acceptable at these stations since the differences between the observed and the simulated stages are still small. The discrepancy of more than 0.5 ft at the gages could be originated from the extrapolated rating curve for high and low flow conditions. Stage profiles were depicted in Figures 39-41.

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLs EVALUATIONS

Figure 41 Simulated water surface profiles along Wekiwa Run and the Wekiwa River

Manning's n values for stream segments close to the headwater and/or relatively high slope, such as upper portions of Rock Springs Run and Little Wekiwa River, were calibrated to 0.035-0.055. The n values for the main stream segments with extensive stream bed vegetation ranged from 0.1-0.2 and varied by flow.

Table 18 Calibrated Manning's n values in the HEC-RAS model

Streams	River Station	Floodplain	Stream	Etc.
Little Wekiwa River	312.14	0.14	0.043	Constant
	250.47-182.49	0.14	0.055	Constant
	143.98-30.50	0.22	0.091 - 0.20	Varied
Rock Springs Run	480.77-459.92	0.15	0.035	Constant
	449.35	0.20	0.05	Constant
	396.13-18.17	0.22	0.075 - 0.17	Varied
Wekiwa Run and Wekiwa River	793.32-711.81	0.22	0.17 - 0.19	Constant
	632.67-455.35	0.22	0.095 - 0.19	Varied
	442.71-0	0.22	0.1-0.2	Varied

4.3 UNSTEADY STATE SIMULATION

4.3.1 Boundary condition for unsteady state simulation

Unlike the steady state simulation, unsteady state simulation requires time-series datasets to replicate stream dynamics at every time step during a simulation period. Hourly water levels gaged at the Lower Wekiva station were used as a downstream boundary condition. Daily discharge data at Rock Springs, Wekiwa Springs and the Little Wekiva River at SR434 stations were used as upstream boundary conditions. Lateral inflows from the drainage area adjacent to stream reaches were used as internal boundary conditions in the HEC-RAS model, and a total of 15 lateral flow time-series was estimated using the HSPF model results and contributing areal ratio to each lateral flow (Table 19).

Table 19 Summary of boundary conditions for unsteady simulation in the HEC-RAS model

Streams	River Station	Boundary Condition Type	Description
Little Wekiva River	312.14	Upstream boundary condition	SR434
	250.47	Lateral inflow hydrograph	Little Wekiva Springs* + Sub25×0.15
	182.49	Lateral inflow hydrograph	Sub25×0.11 + Sub24
	143.98-30.5	Uniform lateral inflow	Sub25×0.74
Rock Springs Run	480.77	Upstream boundary condition	Rock Springs
	350.27-56.34	Uniform lateral inflow	Sub17
	350.27	Lateral inflow hydrograph	Sub14
	18.17	Lateral inflow hydrograph	Sub16
Wekiwa Run and Wekiva River	793.32	Upstream boundary condition	Wekiwa Springs
	747.19	Lateral inflow hydrograph	Sub18
	711.81-579.74	Uniform lateral inflow	Sub19
	508.92-370.65	Uniform lateral inflow	Sub27×0.786
	386.11	Lateral inflow hydrograph	Wekiwa Fall
	370.65	Lateral inflow hydrograph	Sub26
	344.64-322.22	Uniform lateral inflow	Sub27×0.214
	276.66-25.630	Uniform lateral inflow	Sub29

WEKIVA RIVER HYDROLOGY AND HYDRAULIC MODELING FOR MFLS EVALUATIONS

4.3.2 Model Simulation

A short representative simulation period that captures low to high flow events is used to check a model's validity under dynamic conditions. This will alleviate model instability and performance issues. The 6-month period between 1/20/2009 to 7/20/2009 was chosen for the unsteady state simulation. Flow distribution analysis showed that the selected simulation period covers flow exceedance between 0.43% to 93.28% during the period of 2008 to 2016 (Figure 42).

Figure 42 Flow distribution for the Wekiva River at SR46 for the selected unsteady state simulation period (1/20/2009 – 7/20/2009) in between 2008 to 2016

4.3.3 Unsteady state simulation results

The calibrated Manning's n values used in the steady state simulation, which varied by flow, were used in the unsteady state simulation. Simulated and observed water stages were compared at each water level station (Figures 43 – 49 and Table 20). Stage data at ROK2 station were unavailable during the unsteady simulation period. Discrepancy in average stages ranged from 0.02 (at SLB) to 0.26 ft (at Wekiwa Springs). Overall, the unsteady state model matched low, medium and high flow conditions very well. Differences between simulated and observed at the peak stages were -0.32 (at Near Apopka) to 0.24 ft (at SR434), while the discrepancies in the lowest water levels spanned from -0.46 (Little Wekiva River at SR434) to 0.25 (at Railroad). It should be noted that in-stream vegetation changes or any anthropogenic conditions during the unsteady state simulation period could have caused discrepancy between the simulated and observed stages, since Manning's n values were calibrated based on water level profiles from the period of 2008 to 2016.

Table 20 Observed and simulated average, maximum and minimum water levels in the Wekiva River Basin during the unsteady state simulation

5. SUMMARY

The St. Johns River Water Management District (SJRWMD) is to establish minimum surface water flows and levels (MFLs) for priority water bodies (Section 373.042, Florida Statutes (F.S.)). Four water bodies within the Wekiva River system (Wekiva River at SR 46, Little Wekiva River, Wekiwa Springs and Rock Springs) are on the SJRWMD's MFLs priority list. MFLs for the Wekiva River at SR 46 were adopted in 1992 (Hupalo et al 1994), and it is currently under re-evaluation. All four systems are scheduled for adoption by 2019.

The goal of the re-evaluation and determination of Wekiva River Basin MFLs is to ensure that adopted MFLs are based on the most up-to-date criteria, hydrological data and models available. In this study, the previously developed hydrologic and hydraulic models for the Wekiva River system were updated to support the development and re-evaluation of Wekiva River Basin MFLs. The HSPF model simulates the hydrology of the Wekiva River watershed; the HEC-RAS model simulates stream hydraulics in the Little Wekiva River, Rock Springs Run and Wekiva River.

The HSPF model performance was evaluated at 7 stream flow gages for the period of 2003 to 2016. Overall, the results showed good agreement between the simulated and observed flows in terms of the water mass balance, high and low flows, and seasonal flow distribution, which ensured that the model would be applicable for the Wekiva River Basin MFL analysis.

The HEC-RAS model was calibrated under the steady state condition with 13 flow profiles, which were selected from a range of flow conditions between the years of 2008 to 2016. The simulated water surface elevations differed from the observed data by -0.26 to +0.01 ft for the Wekiva River at SR46. The calibrated model was tested under unsteady state simulation for six months in 2009 and showed good agreement between the observed and simulated water levels in terms of low, medium and peak stages. Average flow error for the Wekiva River at SR46 was calculated to be 0.15 ft, while discrepancies in the lowest and peak flow were 0.13 ft and 0.06 ft, respectively.

The HSPF and HEC-RAS models were peer reviewed by two modeling experts in late 2018. Peer review comments were incorporated into the final models and this report.

Overall, the model results indicated that the models are adequate to represent the hydrologic and hydraulic processes in the Wekiva River watershed. Therefore, the calibrated HSPF and HEC-RAS models can be used to assess the MFLs for the Wekiva River systems.

APPENDIX A – DEVELOPMENT OF WEKIVA BASIN SPRINGS FLOWS DATA FOR HSPF MODEL

A major portion of Wekiva River flows comes from springs in the basin. Figure A-1 shows the location of springs in the Wekiva river basin. The springs vary in term of magnitude and available observed data. Table A-1 summarizes the available spring flow data in the basin. The Wekiva river basin HSPF model requires long-term springs flow data for model calibration and MFL simulations.

The gap-filling and extension of springs flow data are based on the available observed data for the springs. The available data were processed as follows:

Group 1: Springs with a relatively long period of record data

Some of the springs in the Wekiva river basin, mainly large springs such as Miami, Palm, Rock, Sanlando, Starbuck, and Wekiva, have a long-term observed data (Table A-1). The flows of these springs were correlated with the Upper Floridan Aquifer (UFA) levels in the region. For these springs, the extension of flow data was based on the water levels of the USGS UFA monitoring well at Orlo Vista (OR-0047 Well). OR-0047 Well is the closest UFA well with the long-term observed groundwater level data. The location of OR-0047 Well is shown in Figure A-1.

The spring flows were related to water levels of OR-0047 Well using the Line of Organic Correlation (LOC) method, also known as Maintenance of Variance Extension. LOC minimizes the errors in both X and Y directions and preserves the characteristics of the probability distribution of the data including the variance and probabilities of flooding and drying events (Helsel and Hirsch, 2002). It is widely used to gap-filling and extending of water levels and flows. LOC function in R software package was used. The LOC regression equations between OR-0047 and spring flows and their coefficient of determinations (r^2) are shown in Table A-2. Figures A-2 through A-7 show the LOC regression plots. Figures A-8 and A-9 show the estimated flows of the largest springs in the basin, Wekiva and Rock springs, respectively.

Group 2: Springs with short period of record

Helen, island, and Sulphur springs have relatively short-term observed data. They are also low magnitude springs (less than 10 cfs). The flow data of these springs were filled in and extended using a simple linear regression (SLR) with nearby larger magnitude springs in the basin. Rock Springs flow data was used to extend the period of record for both Island Springs and Sulphur Springs. Wekiva Springs flow data was used for the extension of the period of record of Helen Springs. Table A-3 presents the linear regression equations and their coefficient of determinations (r^2). Figures A-10 through A-12 present the SLR graphs.

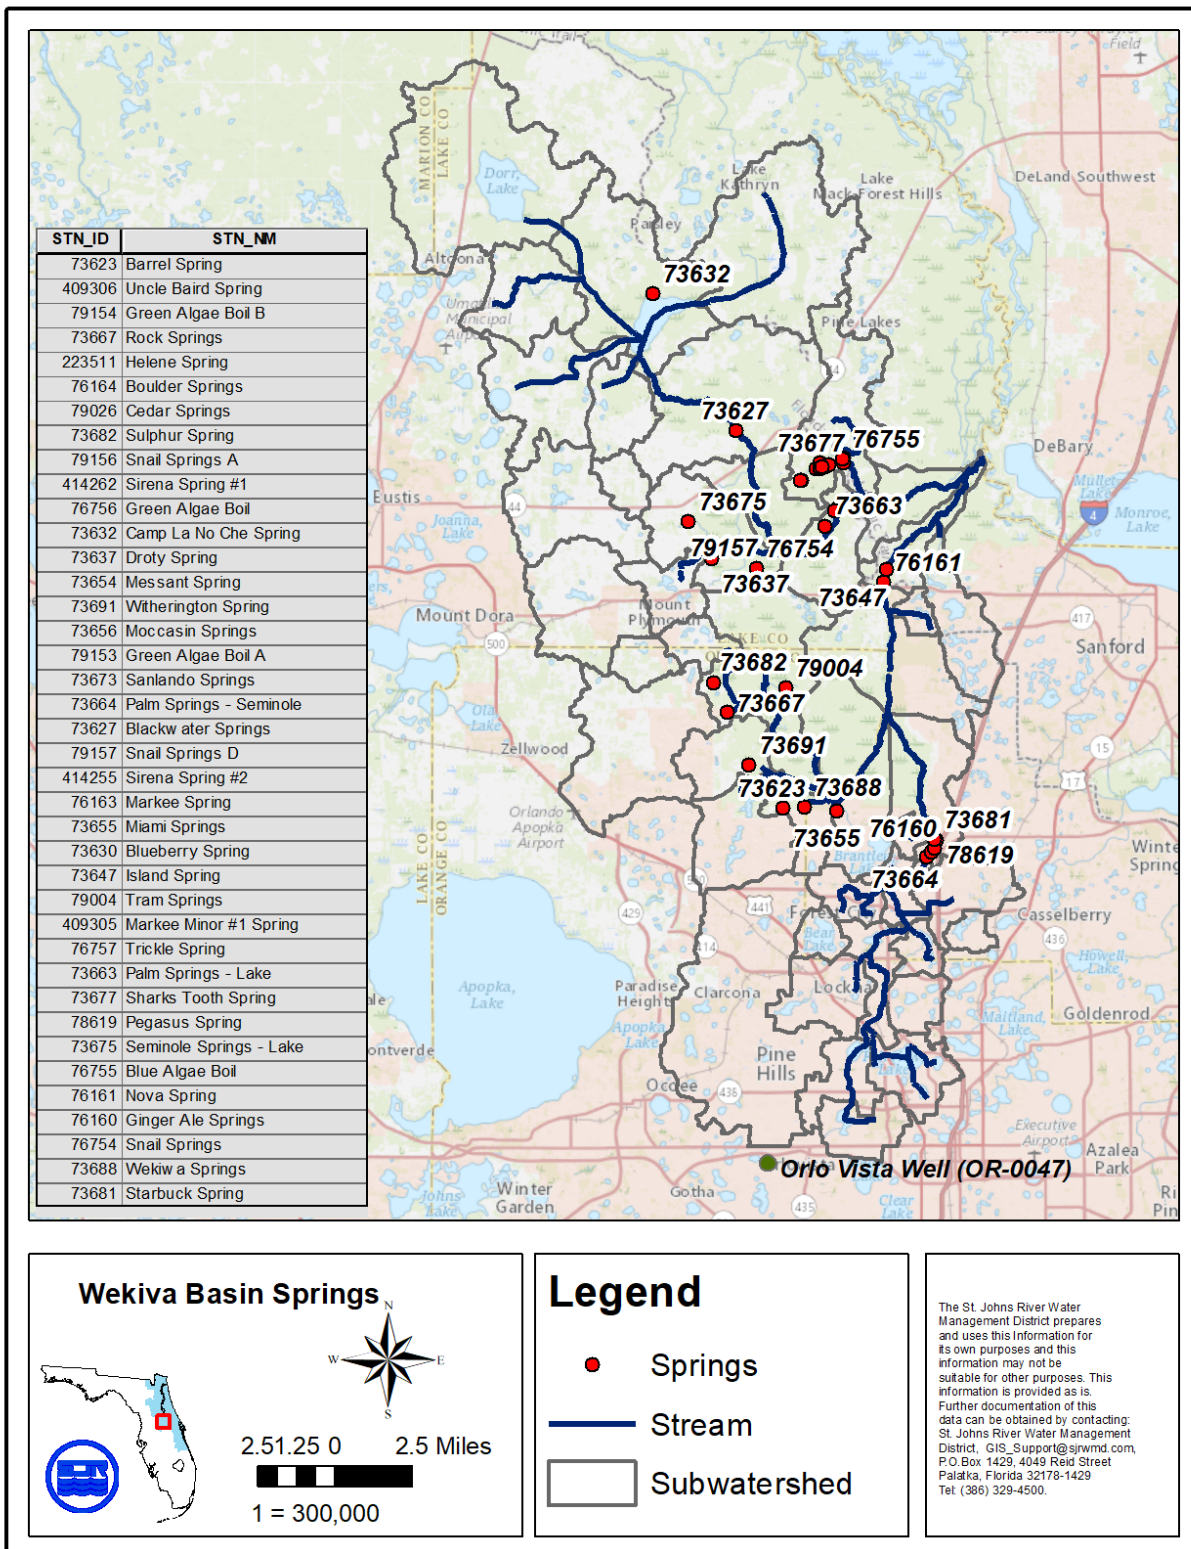

Group 3: All remaining springs

The remaining springs in the basin are characterized by very low flow and have very few observation data. The flows of these springs were estimated using the ratio of mean flows of observation data with the corresponding mean flows of nearby springs. Table A-4 presents these springs with the related nearby springs.

APPENDIX B – HSPF PARAMETERS AND WATER BALANCE

B.1 HSPF Parameters

Parameters were grouped into 5 classes based on geographic and hydrologic similarities. Sub-watersheds for each class are listed below:

Class 1: 1-7, 9, 11

Class 2: 8, 10, 12-13, 17, 19, 24-25, 27, 29

Class 3: 20-21, 28, 30, 32-33, 35-36, 38-44

Class 4: 22-23, 31, 34, 37

Class 5: 14-16, 18, 26

LZSN

Class	1	2	3	4	5	6	7	8	9	10	11	12	13	15
1	5.0209	5.0209	5.0209	5.0209	3.7656	5.6484	5.6484	6.276	6.276	5.6484	7.5313	0.5	0.5	0.5
2	5.0209	5.0209	5.0209	5.0209	3.7656	5.6484	5.6484	6.276	6.276	5.6484	7.5313	0.5	0.5	0.5
3	5.0209	5.0209	5.0209	5.0209	3.7656	5.6484	5.6484	6.276	6.276	5.6484	7.5313	0.5	0.5	0.5
